FORBES, EDWARD, an eminent naturalist, was born at Douglas Isle of Man, February 12, 1815, and died in Edinburgh, November 18, 1854. He received a desultory and imperfect education in early life, in consequence of ill health; but when he left home at the age of 16, he had already possessed himself of a very considerable amount of knowledge in the departments of botany, zoology, and geology. In 1831, F. went to London, with the intention of becoming a student at the Royal Academy; but although he evinced much readiness in drawing, his artistic talents were not sufficiently marked to hold out any prospect of success in the event of his making art his profession; and he therefore determined to turn his attention to medicine, and, with this view, entered the university of Edinburgh. In 1836, he finally relinquished his special medical studies, to devote himself exclusively to the natural sciences. In 1836—1837, he attended lectures at Paris, where he studied under Geoffroy St. Hilaire, Jussieu, and De Blainville, while he at the same time availed himself with diligence of all the advantages afforded to students by the museums and libraries of Paris. From the first year of his college life, F. had spent his summer vacations in rambles over various parts of Great Britain, or excursions on the continent, and the results of the observations which he made during these tours, which were published by him either in the form of separate works, or in the pages of current scientific journals, sufficiently attest his diligence as an observer, and his exact appreciation of analogies and differences of forms. F. may also be regarded as the originator of the use of the dredge, which he employed with equal success in investigating the marine fauna of our own seas, and of the Mediterranean and the Ægean. In 1841, he joined the surveying ship *Beacon*, as naturalist, and accompanied that vessel during the survey of a part of Asia Minor, and co-operated in the exploration of many of the Xanthian cities. On his return to England in 1843, he found that he had, during his absence, been elected to the chair of botany, King's College, London. He was soon afterwards named curator of the Geological Society; and from that period till his removal to Edinburgh, he remained in London, living in a vortex of scientific labors and literary work. In 1844, he was appointed palæontologist to the Museum of Geology in connection with the Ordnance Geological Survey; and in 1851, on the opening of the new buildings in Jermyn Street, London, he was named professor of natural history in the School of Mines. In 1852, he was chosen president of the Geological Society, an honor never before conferred on so young a man; and in 1853, on the death of Professor Jameson, he was elected to the vacant chair of Natural History in the university of Edinburgh. In the summer of 1854, he delivered a short course of lectures—the only one he was destined to give—for at the commencement of the winter session he was seized with a severe illness, which speedily proved fatal, and terminated his life in the 39th year of his age, in the very zenith of his fame, and in the full vigor of his intellectual powers.

F. had been a voluminous writer and a diligent observer of nature from his earliest youth, and had collected an immense mass of materials, many of which were, however, left at his death in a disorganized condition. He did much to advance and systematize special departments of natural history, both by his own labors and by the stimulus which he imparted to his associates and pupils; and it would be difficult to instance any naturalist who has exercised a greater influence on the thought and line of inquiry

pursued by those who have cultivated the same branches of knowledge. His classification of the British *Star-fishes* opened a new era in that branch of zoology; and his discovery that air-breathing molluscs lived at the period of the Purbeck beds, has been the means of rectifying many erroneous hypotheses, and throwing unexpected light on several hitherto obscure points of geology, while the inferences which he drew from the presence of those animals have been fully corroborated. His Report on the *Ægean Sea*, and his observations of the tertiary of Cos, which have proved of great value to geology, raised him to the highest rank among living naturalists. From an early period, he had directed his attention to the distribution of animal and vegetable life in different zones of the sea and land, and his observations in this path of inquiry have opened many new fields of research. F. was a diligent contributor to the current scientific literature of the day, and many of his best papers were written for the meetings of the British Association, of which he was an active member, and for the various societies with which he was connected; while he also took a most efficient share in the labors of the Ordnance Survey during his connection with its staff. His separate works, papers, and monographs, of which upwards of 200 are published, and many of which are copiously illustrated by his own beautiful drawings, cannot be individually specified; but among them we may instance the following: *On the Distrib. of Pulmonif. Mollusca in Europe* (1838); *Malacol. Monensis* (1838); *Star Fishes* (1841); *The Radiata and Mollusca of the Ægean* (1843); *Travels in Lycia* (written in conjunction with Lieutenant Spratt, 1846); *Naked-eyed Medusæ* (1847); *British Mollusca* (1853, 4 vols. 8vo, conjointly with S. Hanley); the Map of *Homoiozoic Belts* (Johnston's *Phys. Atlas*, 1854); *Collection of Literary Papers by E. Forbes* (1855); &c. See *Memoir* by G. Wilson and A. Geikie, 1861.

FORBES, SIR WILLIAM, of Pitsligo, Bart., an eminent Scottish banker, son of Sir William Forbes, Bart., advocate, was born in Edinburgh, April 5, 1739. He succeeded his father when only four years old, and received his education at Aberdeen. In his 15th year, he was introduced into the bank at Edinburgh of Messrs. John Coutts & Co.; and in 1761, was admitted a partner. In 1763, one of the brothers Coutts having died, while another retired on account of ill health, and two others were settled as bankers in London, a new company was formed, consisting of Sir William Forbes; Mr. Hunter, afterwards Sir James Hunter Blair; Mr., afterwards Sir Robert Herries; and Messrs. Stephen and Cochrane. They at first carried on business in the name of the old firm. On 1st January, 1773, however, on some changes in the partnership taking place, the name was changed to that of Sir W. Forbes, J. Hunter, & Co., and of this firm Sir William continued to be the head till his death.

In 1781, he purchased the estate of Pitsligo, Aberdeenshire, which had been forfeited by Lord Forbes of Pitsligo for taking part in the rebellion of 1745. Animated by genuine patriotism and public spirit, he introduced the most extensive improvements on it, and laid out and built the village of New Pitsligo. He was a member, with Johnson, Burke, Garrick, Reynolds, and others, of the celebrated Literary Club of London, and the author of a Life of his friend, Dr. Beattie, the poet, published, with his works, in 2 vols. 4to, in 1805; also of *Memoirs of a Banking House*, being the history of his own, edited by Mr. Robert Chambers (Edinburgh, 1860). He died at his seat near Edinburgh, November 12, 1806, aged 68. By his wife, Elizabeth, eldest daughter of Sir James Hay of Hayston, Bart., he had three sons and five daughters. Universally esteemed and respected, his character is well described by Sir Walter Scott in the introductory address of one of the cantos of *Marmion*. His bank became, in 1830, the Union Bank of Scotland.

FORBES, JAMES DAVID, Principal of the United College in the university of St. Andrews, a grandson of Sir W. Forbes, the banker, was born at Colinton, near Edinburgh, April 20, 1809. He studied in the university of Edinburgh from 1825 until 1830, when he was admitted to the Scottish bar. On the death of Sir John Leslie (q. v.), he was appointed, in 1833, to the chair of natural philosophy in the university of Edinburgh, after a contest in which, among other competitors, he was opposed by Dr. (afterwards Sir David) Brewster and Mr. Galloway. In 1842, the Institute of France enrolled him among its corresponding members. He was, besides, a member of numerous other scientific societies at home and abroad, received the Royal and the Rumford medals from the Royal Society of London, and two Keith medals from the Royal Society of Edinburgh, and was D.C.L. of Oxford. In 1860, F. resigned his chair in Edinburgh, to become Principal of the United College in the university of St. Andrews. Among his contributions to science are—the polarization of radiant heat by the tourmaline, and also by reflection (1836), and its circular polarization—discoveries forming some of the strongest proofs of the identity of calorific and luminous rays; the unequal polarization of heat from different sources (1844); the refrangibility of heat; the depolarization of heat, &c. This whole series of

experimental results is of a very high order of importance. He is, however, best known to the world in general by his researches on the motion of glaciers. See *Travels in the Alps* (1843); *Norway and its Glaciers* (1853); *Tour of Mont Blanc and Monte Rosa* (1855); and *Occasional Papers on the Theory of Glaciers* (1859). He was undoubtedly the first to establish the great fact, that glacier ice moves in its channel like a viscous fluid, the middle moving faster than the sides, and the upper portions faster than the lower. See GLACIERS. In meteorology, F., among other things, improved Wollaston's application of the thermometer to the determination of heights, and verified with great care Fourier's theoretical results concerning the temperature of the ground at different depths and in different kinds of soil and rock. F. also contributed numerous valuable papers to the *Transactions of the Royal Societies of London and Edinburgh*, to the *Edinburgh Philosophical Journal*, and other periodicals. He died Dec. 31, 1868. His *Life and Letters*, edited by Principal Shairp, of St. Andrews, Professor Tait of Edinburgh, and Mr. Adams Reilly the Alpine traveler, was published in London 1873.

FORBES, SIR JOHN, an eminent physician, was born October 18, 1787, at Cattlebrae, Banffshire, and died November 13, 1861. After studying at Aberdeen and Edinburgh, he entered the navy in 1807 as assistant-surgeon, and continued on active duty till 1816, when he finally left the service. In 1817, he took the degree of M.D. at Edinburgh, and soon afterwards settled as a physician at Penzance, from whence he removed in the course of a few years to Chichester. In 1840, F. went to London, where he speedily obtained a large practice. He was knighted in 1853 by the Queen, to whose household he held the appointment of Physician in Ordinary, while he was at the same time Physician Extraordinary to Prince Albert. He was a Fellow of the College of Physicians, and the Royal Society of London; D.C.L. of Oxford, and a member of numerous foreign societies. F., conjointly with Drs. Tweedie and Conolly, was the editor of the *Cyclopædia of Practical Medicine*, which, in addition to the numerous contributions of the editors, included the labors of more than sixty British physicians, of the first rank. This work, which has exercised a most beneficial influence both on the theory and practice of medicine, was completed in 4 vols. 8vo, in 1835. In 1836, F. founded the *British and Foreign Medical Review*, which he carried on with great success for twelve years. The services which he thus rendered to his brother-practitioners placed him deservedly among the foremost of his profession. To F. in a great measure belongs the merit of having introduced the use of the stethoscope in England, and of having successfully directed the attention of British practitioners to the art and practice of physical diagnosis. In 1831, he published the first edition of his translation of Laënnec's *Treatise on Auscultation*; and in 1838, when the fifth edition appeared, the new method was already extensively used. F. was a ready and pleasant writer, as is amply shown by the various records of his summer rambles; among which we may instance his *Physician's Holiday* (1849), and his *Sight-seeing in Germany and the Tyrol* (1856). His last professional work, entitled *Nature and Art in the Cure of Diseases* (1857), contains a systematic exposition of his medical opinions and doctrines.

FORBES MACKENZIE ACT. The statute, popularly known by the name of the gentleman (Mr. Forbes Mackenzie, M.P. for Peeblesshire) who introduced the bill, is the 16 and 17 Vict. c. 67 (1853), entitled 'An Act for the better Regulation of Public-houses in Scotland.' This act retained in general the provisions of 9 Geo. IV. c. 58, by which the granting of certificates by justices of the peace and magistrates, authorizing persons to keep common inns, ale-houses, and victualling-houses in Scotland was regulated. But it prohibited the granting of certificates for excisable liquors to be 'drunk on the premises,' unless on the express condition that no groceries or other provisions to be consumed elsewhere should be sold in the house or premises with respect to which such certificate is granted. The object of this portion of the enactment being to prevent grocers from becoming in reality the keepers of tipping-houses, those persons continued to be permitted to sell liquors by retail, provided that they were not consumed in their shops.

In accordance with the principle of distinguishing between the different classes of houses in which the trade of a spirit-dealer should be carried on, three different grades of licenses were introduced: those applicable, viz., 1, to inn or hotel keepers; 2, to public-house keepers; and 3, to grocers and provision-dealers. As regards the first class, it is enacted that they shall not 'keep open house, or permit or suffer any drinking in any part of the premises belonging thereto, or sell or give out therefrom any liquors before eight o'clock in the morning, or after eleven o'clock at night of any day, with the exception of refreshments to travellers, or persons requiring to lodge in the said house or premises; and further, that they shall not open their houses for the sale of any liquors, or sell or give out the same on Sunday, except for the accommodation of lodgers and *bonâ-fide* travelers. The same

restrictions are imposed on the second class of persons—viz., the keepers of public-houses, with this addition, that no exception is made in their case in favor of travelers or lodgers; whilst grocers and provision-dealers, in addition to the prohibition to open on Sundays, and that already mentioned with reference to the consumption of spirits on the premises, are forbidden 'to sell or give out any liquors before six o'clock in the morning, or after eleven o'clock at night.' Separate licenses were also introduced for the sale of malt liquors from those applicable to the sale of wine and spirits, all of which had formerly been included under one license. By this statute, also, for the first time in Scotland, the very formidable power was conferred on the police of entering at any time any public-house, or house where refreshments are sold to be consumed on the premises, and penalties were awarded against those who refused to admit them, or who obstructed their entrance. These provisions having given rise to much discussion, a Royal Commission to inquire into the working of the act was issued on the 25th April 1859. The result of the commission was the issue, as usual, of two enormous volumes of printed evidence, and of a report, more distinguished for its length than for the value of the suggestions which it contains. The commissioners arrived at the conclusion, that 'although intemperance still prevails to a lamentable extent, it would seem that this vice has been for some time gradually descending in the scale of society, and that it is now chiefly confined to the lowest class of the population.' This effect the commissioners ascribe to several causes, of which the first and most important is the increase of the duty on excisable liquors from 2s. 4d. per imperial gallon, at which it stood in 1823, to 8s., to which it had been raised in 1855. Nor do they deny to the Forbes Mackenzie Act its share of merit. 'The beneficial effect of the act,' they say, 'is proved by the evidence which we received as to the diminution of crime, and the change for the better in the habits of the people, immediately after the passing of the act, when its provisions were strictly enforced, and by the tendency in an opposite direction which in some places has followed its less rigorous enforcement. Whilst thus generally approving of the act, the commissioners suggest a number of alterations, mostly with the view of enabling the police to carry out its provisions with greater efficiency.

In reference to the difficulty experienced by hotel-keepers in ascertaining what persons come under the description of *bona-fide* travelers, the commissioners recommend that 'persons inducing hotel-keepers to sell or give out excisable liquors to them on Sunday, by falsely representing themselves as travelers, should be guilty of an offence, and be liable, on conviction, to a fine.' This recommendation was given effect to in the Public-Houses Amendment Scotland Act 1862, which imposes a penalty of £5 or thirty days' imprisonment on persons obtaining excisable liquor on false representations on Sunday, or before opening or after closing hours. In these circumstances, it becomes important to know that it has been decided in England that to constitute a 'traveler' within the meaning of the corresponding Act 18 and 19 Vict. c. 118, s. 2, it is a matter of indifference whether the parties be traveling for business or pleasure, and that a walk, ride, or drive, for exercise and amusement of such length as to render refreshments desirable, is a sufficient journey. In *Atkinson v. Sellers* (5 C. B. N. S. 442), Chief Justice Cockburn remarked, that 'a man could not be said to be a traveler who goes to a place merely for the purpose of taking refreshment. But if he goes to an inn for refreshment in the course of a journey, whether of business or of pleasure, he is entitled to demand refreshment, and the innkeeper is justified in supplying it.' See also *Taylor v. Humphreys*, C. P. 705; 4 L. T. N. S. 314. The first was in the case of a drive from Liverpool of 5½ miles, the second of a walk from Birmingham of 4 miles.

FORBIDDEN FRUIT, a name fancifully given to the fruit of different species of *Citrus*. In the shops of Britain, it is a small variety of the Shaddock (q. v.) which generally receives this name. But on the continent of Europe, a different fruit, regarded by some as a variety of the orange, and by some as a distinct species (*Citrus Paradisi*), is known as the Forbidden Fruit, or Adam's Apple. Like some other fruits of the same genus, it was recently introduced into the south of Europe from China. The tree has broad, tapering, and pointed leaves, the leaf-stalks winged; the fruit is large, somewhat pear-shaped, greenish-yellow, of very uneven surface, having around its base a circle of deeper depressions, not unlike the marks of teeth, to which it probably owes its name. It is chiefly the rind which is the edible part; the rind is very thick, tender, melting, and pleasant; there is very little pulp; the pulp is acid.

The name Forbidden Fruit has also been given to the fruit of *Tabernaemontana dichotoma*, a tree of Ceylon, of the natural order *Apocynaceae*. The shape of the fruit—which is foliaceous, containing pulp—suggests the idea of a piece having been bitten off, and the legend runs that it was good before Eve ate of it, although it has been poisonous ever since.

FORCE; ENERGY. Till we know what Matter (q. v.) is, if there be matter, in the ordinary sense of the word, at all, we cannot hope to have any idea of the absolute nature of force. Any speculations on the subject could only lead us into a train of hypotheses entirely metaphysical, since utterly beyond the present powers of experimental science. If we content ourselves with a definition of force based on experience, such a definition will say nothing of its nature, but will confine itself to the effects which are said to be due to force, and in the present state of our knowledge it is almost preposterous to aim at more.

Our first ideas of force are evidently derived from the exertion required to roll, or lift, bend or compress, &c., some mass of matter; and it is easy to see that in all such cases where muscular contraction is employed, matter is moved, or tends to move. Force, then, we may say generally, is *any cause which produces, or tends to produce, a change in a body's state of rest or motion.* See **MOTION, LAWS OF.** The amount or magnitude of a force may be measured in one of two ways: 1. By the pressure it can produce, or the weight it can support; 2. By the amount of motion it can produce in a given time. These are called respectively the *Statical* and *Dynamical* measures of force. The latter is, as it stands, somewhat ambiguous. What shall we take as the quantity of motion produced? Does it depend merely on the velocity produced? or does it take account of the amount of matter to which that velocity is given? Again, is it proportioned to the velocity itself, or to its square? This last question was very fiercely discussed between Leibnitz, Huyghens, Euler, Maclaurin, the Bernouillis, &c.; Leibnitz being, as usual with him in physical questions, on the wrong side. Newton, to whom we owe the third law of motion, had long before given the true measure of a force in terms of the motion produced. This law is an experimental result—that when pressure produces motion, the *momentum* produced (see **MOMENTUM**) is proportional to the pressure, and can be made (numerically) equal to it by employing proper units. Hence momentum is the true dynamical measure of force, which, therefore, is proportional to the *first* power only of the velocity produced. What is properly measured in terms of the *square* of the velocity, we shall presently see. For various properties of force, statical and dynamical, see the following articles: **COMPOSITION OF FORCES, COUPLES, CENTER OF GRAVITY, CENTRAL FORCES, FALLING BODIES, MECHANICAL POWERS, VIRTUAL VELOCITIES.**

It is obvious that in order to produce any effect at all, or to do **WORK**, as it is technically called, a force must produce *motion* i. e., must move its point of application. A weight laid on a table produces no effect whatever, unless the table yields to the pressure, i. e., unless the weight descends, be it ever so little. We do no work, however much we may fatigue ourselves, if we try to lift a ton from the floor; if it be a hundredweight only, we may lift it a few feet, and then we shall have done work—and it is evident that the latter may be measured as so many pounds raised so many feet—introducing a new unit, the **FOOT-POUND**, which is of great importance, as we shall shortly see, in modern physics. See **WORK.** This is evidently, however, a statical measure of work, since no account is taken of velocity. Have we then for work, as we had for force, a *dynamical* measure?

Let us take a simple case, where the mathematical investigation is comparatively very easy, and we shall find we have. We know (see **VELOCITY; MOTION, LAWS OF**) that if a particle be moving along a line (straight or not), and the distance moved (in the time t) along the line from the point where its motion commenced be

called s , its velocity is $v = \frac{ds}{dt}$. Also we know that the force acting

on it (in the direction of its motion) is to be measured by the increase of momentum in a given time—this gives (just as the last

equation was obtained) $F = m \frac{dv}{dt}$. From these two equations, we

have, immediately, $mdv = Fds$, or as the rudiments of the differential calculus give at once, $\frac{mv^2}{2} = \int Fds = F.s$ if the force be uniform.

The quantity on the right-hand side is the sum of the products of each value of F , by the corresponding space ds , through which the particle moved under its action. It is therefore the whole work done by the force. On the left hand, we find half the product of the mass, and the square of the velocity it has acquired; in other words, the *vis-viva*. Hence, in this case, the *vis-viva* acquired equals the amount of work (q. v.) expended by the force.

It appears from a general demonstration (founded on the experimental laws of motion, and therefore true, if they are), but which is not suited to the present work, that if, in any system of bodies, each be made up of particles or atoms, and if the forces these mutually exert be in the line joining each two, and depend merely on the distance between them, then we can express the required proposition in the following form:

Any change of vis-viva in the system corresponds to an equal amount of work gained or lost by the attractions of the particles on each other.

What is spent, then, in work, is stored up in vis-viva; and conversely the system, by losing some of its vis-viva, will recover so much work-producing power. If we call the former, as is now generally done, *Kinetic*, and the latter *Potential Energy*, we may express the above by saying, that in any system of bodies where the before-mentioned restrictions are complied with, *the sum of the kinetic and potential energies cannot be altered by the mutual action of the bodies*. The most simple and evident illustrations of this proposition are to be found in the case of the force known as gravitation. The potential energy of a mass on the earth's surface is zero, because, not being able to descend, it has, in common language, no work-producing power. If it be raised above the surface, and then dropped, it is easy to see that the work expended in raising it will be exactly recovered as vis-viva after its fall. For (see FALLING BODIES) a mass falling through a space, h , to the earth acquires a velocity v , such that $v^2 = 2gh$, or if m be the mass, $\frac{mv^2}{2} = mgh$. The left-hand side gives the vis-viva acquired by the fall—the right is the product of the weight (mg) and the height fallen through—or is the work required to elevate the mass to its original altitude.

Hence we may calculate the amount of work which can be obtained from a head of water in driving water-wheels, &c., remembering, however, that there is always a *loss* (as it is usually called) due to friction, &c., in the machinery. That there is a loss in useful power, is true, but we shall find presently that in energy there is none, as indeed our general result has already shown. Where the apparently lost energy goes, is another question.

Another good example of potential energy is that of the weights in an ordinary clock. It is the gradual conversion of potential into kinetic energy in the driving weight which maintains the motion of the clock, in spite of friction, resistance of the air, &c.; and we have in the kinetic energy of sound (which depends on vibrations in the air) a considerable portion of the expended potential energy of the striking weight. A coiled watch-spring, a drawn bow, the charged receiver of an air gun, are good examples of stores of potential energy, which can be directly used for mechanical purposes.

The chemical arrangement of the different components of gun-powder, or gun-cotton, is such as corresponds to enormous potential energy, which a single spark converts into the equivalent active amount. But here, *heat* has a considerable share in the effects produced; it may then be as well, before proceeding further, to consider how we can take account of it, and other (so-called) physical forces, as forms of energy.

Correlation of Physical Forces.—So far as we yet know, the physical forces may be thus classified: I. GRAVITATION (q. v.); II. MOLECULAR FORCES—COHESION (including CAPILLARITY); ELASTICITY, CHEMICAL AFFINITY; III. HEAT AND LIGHT; IV. ELECTRICITY (including MAGNETISM); V. ANIMAL FORCE; VI. VITAL FORCE, having, as some most irrationally suppose, an analogue in inorganic masses, which may be called Crystalline Force. (This idea is examined further on). Of these, I., II., and some forms of III., are more immediately connected with *matter* than the others—that is to say, that the remainder almost necessitate the hypothesis of the existence of some medium unlike ordinary matter, or, in popular language, an *imponderable*. The almost universal opinion of physicists, however, seem to be, that even the former must be accounted for in such a way. Newton, in his second letter to Bentley, says, with respect to gravitation (and it is obvious that similar language is applicable to molecular forces generally): 'You sometimes speak of gravity as essential and inherent to matter. Pray, do not ascribe that notion to me, for the cause of gravity is what I do not pretend to know.' And again in the third letter: 'It is inconceivable that inanimate brute matter should, without the mediation of something else, which is not material, operate on, and affect other matter without mutual contact, as it must do, if gravitation, in the sense of Epicurus, be essential and inherent in it; and this is one reason why I desired you would not ascribe innate gravity to me. That gravity should be innate, inherent, and essential to matter, so that one body may act upon another at a distance through a vacuum, without the mediation of anything else, by, and through which their action and force may be conveyed from one to another, is to me so great an absurdity, that I believe no man who has in philosophical matters a competent faculty of thinking, can ever fall into it.'

'Gravity must be caused by an agent acting constantly according to certain laws; but whether this agent be material or immaterial, I have left to the consideration of my readers.' Of what that medium may consist, we cannot, of course, hazard even a conjecture; but if it be composed of separate atoms—i. e., not continuous—it is evident that a second medium will be required to help the particles of the first to act on each other (for without this, the first medium would be merely obstructive), and so on.

This must stop somewhere; why not, then, at the first? But in the present state of our knowledge of mechanics, a continuous medium is barely conceivable, and its motions, &c., present considerable difficulties to even plausible mathematical treatment. If we take the view opposed to Newton's, as Mosotti and others have done (their ideas are considered further on), we can, in a very artificial manner, however, account for gravitation and molecular action; but, as before said, the foundations of this attempt at explanation are hardly tenable.

Just as sound depends on the elasticity of the air and vibrations thereby maintained and propagated, light and radiant heat, which are certainly identical, most probably consist in the vibrations of some very elastic fluid. This has been provisionally named Ether (q. v.). If it be continuous, it may help us to account for the first two categories of force, also, as we have already seen; if not so, as is more likely, fresh difficulties arise. Light and heat, however, undoubtedly depend on motion, and correspond, therefore, to so much vis-viva or actual energy. Even heat in a liquid or solid body must correspond to some vis-viva in the material particles, since a hot body can give out both light and heat, and a body may be heated by luminous or calorific rays which are vibratory, as we have seen.

Class IV. contains perhaps the most puzzling of all these forces. That there is something in common in all the forms of electricity, and that magnetism is nearly related to them, is certain; it is probable, also, that frictional electricity, when statical, consists in something analogous to a coiled spring, or is a form of potential energy—the others being forms of kinetic energy. Some have supposed magnetism to be also a form of potential energy, but Ampere's discoveries have materially lessened the probability of the truth of this hypothesis. We shall consider this again.

Class V. may be deferred for the present.

As to Class VI., it seems, from the observations of physiologists as to the formation of cellular matter, and the production in living organisms of compounds which have not yet been made by ordinary chemical processes, that the vital force, if there be such, is not a force which does work, in the mechanical sense of the term, but merely *directs*, as it were, the other natural forces *how to apply* their energies. Were a railway train running on a smooth horizontal line of rails, it would retain for ever its original velocity; but on turning a curve it would be acted on by deflecting forces, without which its path would be straight. These forces *do not work*, as is evident, since this would be shown in alteration, of the vis-viva, and none takes place. They modify however, the direction in which the train moves.

When gangs of laborers and masons are at work building an edifice, the former are employed raising stones, mortar, &c., the latter in laying them; but there is present an overseer with a plan, who, doing no (mechanical) work himself, guides and directs the proper application of force by the working body. In this view of the case, the laborers are the physical forces, and the overseer the vital force. It is quite certain that the so-called crystalline force cannot properly be put in this category, as presenting even an analogy, however slight; it is probably an effect, not a cause, and due to the different forms of simple or compound particles of matter, and the consequent variations in their molecular forces in different directions.

So far, then, for the possible nature of the forces, which, with the probable exception of VI., certainly depend on various forms of energy. Can these be transformed one into another, as the different kinds of mechanical energy can? Take the potential energy of gravitation to begin with. We can employ it to drive a water-wheel. This turns a shaft, to which, if a tight brake be applied, heat will be produced by friction, and light also, if a rough wheel on the shaft be made to rotate against a piece of flint or pyrites; or electricity may be produced by employing the moving power to turn an ordinary electrical machine, or a magneto-electric one; and from the electricity so produced, electrical charges and currents may be derived; from them heat and light again. Or the currents may be employed to magnetize a needle or a piece of soft iron, or to produce chemical decomposition.

Again, heat may be employed by means of a steam-engine as a substitute for the water-power or potential energy of gravitation, and the above effects be produced. It may also be employed in raising weights, and therefore in producing the potential energy in question; or it may be employed to produce Thermo-electric Currents, and thence all the ordinary effects of electricity, including the motion of a magnetic needle.

Light may be employed to produce chemical combination or decomposition, as we see in photography; it may also by the same means be made to produce electric currents, and consequent *motion* of a needle. It is not yet proved that light can produce magnetism *directly*, though there can be little doubt that, if properly applied, it is capable of doing so.

Chemical action in a voltaic battery can be made to produce motion, heat, light, electricity, electrical charges and magnetism, and to overcome other chemical affinity.

Capillary action has been employed to produce electricity, and mechanical effects, &c., but we need not go through the whole category.

In these experimental results, then, consists what is called the Correlation of the Physical Forces—i. e., the transmutability of one of the latter into another or others. The idea is old, but the proofs of its truth have only become numerous within the last half-century. Grove has published an excellent treatise with the above title; to this we refer the curious reader for further detail on this interesting subject.

Conservation of Energy.—But a far more important principle, being, in fact, the precise statement of the preceding—which is somewhat vague—is that of the Conservation of Energy. It is simply the extension (to all physics) of the principle which we have given in full, and proved in a particular case, at the beginning of this article—i. e., that the sum of the potential and kinetic energies of any set of moving bodies cannot be altered by their mutual action. Let us now suppose heat, light, &c., to consist in the energy of vibratory movements of particles, and in their relative states of distortion, &c., and make the supposition that these particles act on each other—no matter by what means—in the line joining each two, and with forces which depend on their distance, and we have at once the theorem, that the sum of the potential and kinetic energies is a quality unalterable in any system, save by external influences. Hence, when mechanical power is said to be lost, as it is by the unavoidable friction in machinery, &c., it is really only changed to a new form of energy—in general, heat. Thus, when a savage lights his fire, he expends animal energy in rubbing two pieces of dry wood together. If these pieces of wood were not in contact, no force would be required to move them past each other—more and more is required as they are more strongly pressed together. The equivalent of the energy so expended is found in the heat produced. Davy showed that two pieces of ice might be melted by rubbing them together. A skilful smith can heat a mass of iron to redness by mere hammering. Here the energy actually employed is partly given out in the shape of heat, and partly stored up in the iron as potential energy due to the compression of the mass, or the forcible approximation of its particles. Amongst the earliest, and certainly the best experiments on this subject, are those of Joule (q. v.). He determined the relation between the units of heat and potential energy of gravitation, by various methods, which gave very nearly coincident results. One of these we may mention. A paddle-wheel is so fixed as to revolve in a closed vessel full of water. The wheel is driven by the descent of a known weight through a measured space, and precautions are taken against losses of energy of all kinds. The water agitated by the paddle-wheel comes soon to rest, as we know; but this is due to friction between its particles; and the final result is the heating of the water. The quantity of water, and also the number of degrees by which its temperature is raised, being measured, a simple proportion enables us to find how many foot-pounds (see FOOT-POUND) of mechanical energy correspond to the raising by one degree the temperature of a pound of water. The result is, that the heating a pound of water one degree Fahrenheit is effected by 772 foot-pounds—and this number is called Joule's Equivalent. In other words, if a pound of water fall to the ground through 772 feet, and be then suddenly arrested, its temperature will be raised one degree; and, conversely, the heat that would raise the temperature of a pound of water one degree, would, if applied by a steam-engine or otherwise, raise 772 pounds one foot high. Now (see the article HEAT), we know the amount of heat which is produced by the burning (in air) of any material whose composition is known.

It follows then, that from the mere quantity and composition of a substance, we can tell the amount of mechanical work due to its combustion; that is, supposing it all to be effective. As we have been led to the mention of heat of combustion, let us consider what this is due to. Combustion (in air) is merely a chemical combination of the constituents of the burning body with oxygen—the heat and light which are developed are therefore, by the conservation of energy, equivalent to the excess of potential energy of the uncombined, over the combined, oxygen and combustible.

That this is the real state of the case—and that the original setting fire to the combustible has nothing to do with the matter, as is frequently imagined—will be made evident by considering any spontaneous combination, say that of chlorine and copper filings, or of mercury and sodium, &c., in which cases the potential energy lost by the compound appears as heat, light, and sometimes sound.

The equivalents of the other forms of energy have not been even approximated to, with the exception of that of light. Thomson has determined the energy of a cubic mile of sunlight at the earth to be somewhere about 12,000 foot-pounds, giving about 10,000 as the Horse-power (q. v.) of each square foot of the sun's surface. There are some additional difficulties in the way when we seek the equivalent of electric energy, for here the question

arises: 'Is there a special substance which is, or the energy of whose motions is, electricity, or does it depend upon motions and distortions of the luminiferous ether?' for we can scarcely suppose it to be due to motions of the particles of matter. If the first, we have as yet no means of estimating its energy; if the latter, we may consider it as within the reach of experiment. It may merely be remarked here, that Weber's exquisite theoretical statement of electric laws—resting on the fundamental assumption that there are two *electric fluids*—requires the admission of mutual forces, which vary with the relative velocity of its particles, and for which, therefore, the conservation of energy does not necessarily hold.

Helmholtz, in an admirable paper (*Ueber die Erhaltung der Kraft*, translated in Taylor's *Scientific Memoirs*, New Series, i.), starting from the assumptions above explained, has applied the principle of conservations of energy to the investigation of many recondite problems connected with the physical energies. We cannot, of course, enter into his work in detail, as it is somewhat analytical, but we may freely borrow such of its contents, as we have not already alluded to, at least such as will suit the plan of this article.

A very good example of the conservation of energy is found in the increasing velocity of a planet or comet as it approaches the sun, and thus loses potential energy; and also in the fact, that in the case of these bodies the mere distance from the sun, and the velocity at that distance, enable us to tell at once the nature of the orbit described—i. e., which of the conic sections it is.

Latent heat has probably a form of potential energy, depending on the physical state of the substance in which it is stored up. The same may be said of those substances which, when mixed, produce heat or cold, as water and sulphuric acid, or nitrate of ammonia. It is easily seen that here the heat or cold depends upon a change of molecular arrangement of some kind; that is, a change of the potential energy.

In magnetism and statical electricity, of course, the conservation of energy holds, as we know that all the phenomena can be explained by attractions and repulsions, following the law of gravitation. In the discharge of a Leyden battery, the potential energy lost is reproduced as heat in the connecting wires, and as light, heat, and sound with the disruptive spark. In charging a Leyden jar by means of the electrophorus, the charge is directly produced by the expenditure of mechanical work in overcoming the attraction of the negative electricity of the resinous plate for the positive electricity of the cover.

In the ordinary voltaic battery, the excess of loss of potential energy in the cells by the chemical union, say of zinc and oxygen, and of sulphuric acid and oxide of zinc, over that gained by the decomposition of water, produces the kinetic energy of the current, which may be transformed into heat, light, magnetism, or motion, or two or more. Or it may be employed to reproduce potential energy by chemical decomposition, say that of water. This again, by a spark, can be reconverted into kinetic energy as an explosion accompanied by heat, light, and sound. While an electric current causes the motion of a magnetized needle, our general principle should lead us to infer that the current itself will be weakened. This is found to be the case, but, as it should be, *only during the motion* of the needle. The needle in a permanent state of deflection produces no effect whatever. Now, the diminution of an electric current is simply equivalent to the addition of a weaker current passing in the opposite direction. We should expect, then, that the motion of a magnet near a conducting wire will in general produce a current in the latter, and this is, in fact, Faraday's great discovery of magneto-electric induction. In this case, the current ceases so soon as the magnet ceases to move relatively to the wire.

If a mass of copper or other good conductor be set in rapid rotation near a powerful magnet, the motion produces electric currents in the copper, which, being attracted by the magnet, soon bring the mass to rest. It is not so clear in this case into what the mechanical energy of the rotation has been transformed, especially as the electric currents cease with the motion; but if we keep up the rotation forcibly, we find in a short time the copper growing warm; in other words, the energy has been transformed into electric currents, and the latter into heat. This very beautiful experiment is due to Joule, and has been repeated in a striking popular form by Foucault.

Advantage has been taken by Faraday of the phenomena of induction, to produce electric currents by aid of the earth's magnetism. His apparatus is simply a revolving disc of metal, and the terminal wires touch, one its axes, the other its edge. The energy which is here transformed into electric currents is the additional effort requisite to turn a *conducting* disc, instead of an equal *non-conducting* one. It is a curious consequence that in all metallic machinery a portion of the energy of the prime mover is lost in producing electric currents, and finally heat, in the moving parts, so that heat in such cases is not entirely, though very nearly, due to friction alone.

Perhaps one of the most singular of these transformations of energy is that already referred to of heat into electric energy. Certain crystals, such as tourmaline, become electrified by heat; but electric currents can be produced by simply heating a *junction* of two wires or bars of different metals, the other ends also being in contact. Now, if we were to heat the other junction, it is obvious that, as at it the metals are arranged in the opposite order, we should produce a contrary current; conversely, by cooling them we should strengthen the first. But the conservation of energy requires that such a junction should be heated or cooled according to the direction in which a current passes through it. This was discovered by Peltier.

Animal energy is simply a transformation of the potential energy of food. This is well illustrated by the increased diet which is required when man or beast abruptly changes from a state of inactivity to one of toil, as with a polar bear after his winter's sleep; or by the greater amount and better quality of food which are necessary for criminals subject to hard labor, than for those who are merely imprisoned.

Since, then, as far as we have yet seen, there is no such thing as gain or loss of energy anywhere, while it appears that the ultimate transformation of such energy is heat, and that the latter tends to a uniform diffusion or dissipation, in which it is unavailable, as far as we know, for further transformation (see *HEAT*), whence do we procure the supplies of energy which are requisite to maintain the economy of life? We answer: Chiefly, or indeed entirely, from the sun, whence they come as light and radiant heat, perhaps in other forms. Without the sun, where would be vegetation?—without the latter, where animal life? Where would be our stores of fuel, whether wood or coal? It is entirely then, we may say, to the directly supplied energy of the sun that we look for the maintenance of life; and this leads to a question not of much importance to ourselves, to be sure, but of vast future consequence to the human race: Is this supply finite? Will the sun in time have given off all its energy, or is it continually receiving accessions itself, and if so, has it an inexhaustible store to draw from?

Now, whether the sun be a hot mass, or be surrounded by an atmosphere in an intense state of combustion, or whether it derives the main part of its heat, as Thomson supposes, from gravitation (in a way presently to be considered), it is certain that, as far as we know, it must at some period be exhausted. Such is the apparently inevitable verdict of the conservation of energy.

The gravitation theory of the origin of energy generally may be given in some such form as this: The matter in the universe, in a state of coarser or finer division, originally filled all space, and possessed, therefore, by virtue of gravitation, a certain amount of potential energy. As particles gradually moved up to each other, and became slowly agglomerated into masses, more and more of this energy was realized in its kinetic form; some as heat (that of the sun, or the internal heat of the earth, &c.), some as vis-viva of axial or orbital rotation, &c. There still remains unagglomerated in space (see *ZODIACAL LIGHT, AEROLITES, COMETS, NEBULÆ*) much of this original matter still falling mainly towards the larger masses, as the sun and stars, and exchanging its potential for kinetic energy. But the latter, as we have seen, tends ultimately to become heat, and to seek a uniform diffusion. This, then, it appears, is to be the last scene of the great mystery of the universe—chaos and darkness as 'in the beginning.'

An immediate consequence of the truth of the conservation of energy is the impossibility of what is usually understood by the Perpetual Motion (q. v.); for it is to be carefully remembered that perpetual motion, in the literal sense of the words, is not only possible, but very general. If there were no such thing as friction, or if we had a perfectly smooth body, in the form of the tectonum, for example, it would spin for ever in vacuo with undiminished speed. The earth in its axial rotation affords a good example. Were it a perfect sphere, and of uniform material, the other masses of the system could produce no effect whatever on its rotation, and the latter would remain for ever unchanged. And even, as we have already seen, when one form of kinetic energy, as electricity, or ordinary vis-viva, is lost, we find it reappearing in other forms of kinetic energy, such as heat and light. But this is not the technical acceptance of the term, the perpetual motion; it is popularly understood to mean a source of motion which will not only preserve its own vis-viva unchanged, but also *do work*. This is, of course, incompatible with the conservation of energy, for wherever work is done, equivalent energy in some form or other is consumed. The ordinary attempts to obtain 'the perpetual motion' which are still being made in thousands by visionaries, are simply absurd, based as they are for the most part on ignorant applications of mechanics. There is absolute impossibility here; 'and a perpetual motionist' of the common herd is far more infatuated than a 'squarer of the circle;' for the latter's problem *may* be solved, though certainly not by the means usually employed, or in the form usually sought for.

We may now briefly consider the chief theories of the various forms of energy which have been advanced of late times. All of them assume at the outset forces of attraction or repulsion between particles, or else a highly elastic fluid, or rather solid, if we may so call it, in which the particles of matter float, or are imbedded. We have already considered the difficulties attending the latter supposition; but it is the only one which does not refer force back to force, thus apparently leaving the question where it found it. We may dismiss it with the remark, that a fluid or quasi-solid absolutely continuous and alike in every part is difficult to conceive; and it is hard to understand how motion can be propagated through it.

If it be not continuous, forces must be supposed to be exerted by its parts on each other, else the motion of one part would not affect the others. There is one way in which the latter difficulty has been attacked, which seems plausible enough; and that is, that the particles of this fluid are in a state of rapid motion, and continually impinging on each other and on the particles of matter, no forces being exerted except those of pressure at the impact. This is the notion of Le Sage. But, unless these particles be supposed *elastic*, their motion would be lessened at every impact, and destroyed completely if the impact were direct. This objection seems to be a very strong one. The first-mentioned theory, that of Epinus and Mosotti, assumes that material particles float in a general atmosphere of ether, that the particles of each repel one another, but that a particle of matter attracts one of ether. From these suppositions, and an hypothetical law connecting pressure with density in such an ether, Mosotti has deduced gravitation and the molecular forces; but to apply the hypothesis to the other physical energies, other suppositions are necessary. These have been supplied by Clausius and Redtenbacher, who, with the assumptions of particles of matter and of ether as before, imagine those of matter to attract each other, and also those of ether, but the latter to be mutually repulsive. Light and radiant heat, according to this theory, are vibrations of the ether which fills all space between the particles of matter, or rather, between the atmospheres of ether which, by the foregoing assumptions, the particles of matter will collect about them. Heat consists of vibrations of the molecules of matter, or of the groups of atoms (see *ATOMIC THEORY*) of which the molecule of a compound body is built up, together with their atmospheres. Electricity, magnetism, &c., are explained to be rotations in the atmospheres. Redtenbacher and Clausius are not quite agreed as to the physical energies corresponding to each of these forms of motion, but the above sketch will give a general idea of the nature of their speculations.

But the most startling of all the reflections on force, and its ultimate nature, which have perhaps ever been made, are those of Faraday. Without calling in question in ordinary cases the truth of the conservation of energy, he has endeavored, by experiment (the only genuine test in a question so novel and so profound), to prove what may be called the Conservation of Force. Here we understand *force itself*, and *not energy*. He argues thus: Two masses, according to the undisputed law of gravitation, attract with four times their mutual force if their distance be diminished to half; and with only one-fourth of the same, if their distance be doubled. He asks *whence* comes the additional force in the former, and *what becomes* of the lost force in the latter case?

Now, it is evident that this is a new question, totally distinct from any we have yet considered. To answer it we must know *what* force is. Would gravitation have any existence if there were but one particle of matter in the universe, or does it suddenly come into existence when a second particle appears? Is it an attribute of matter, or is it due to something between the particles of matter? Faraday has tried several experiments of an exceedingly delicate kind, in order to get at some answer to his question. A slight sketch of one of them must suffice.

A pound-weight is not so heavy at the ceiling of a room as it is when on the floor; for, in the former case, it is more distant from the mass of the earth than in the latter. The difference for a height of 30 feet is (roughly) about $\frac{1}{350,000}$ th of a pound. Now, if a mass of metal be dropped through such a space, an additional force, $\frac{1}{350,000}$ th of its weight, is called into play, and the object of the experiment was to detect whether electrical effects accompanied this apparent *creation* of force. The mass, therefore, was a long copper wire, whose coils were insulated (see *ELECTRICITY*) from each other, and whose extremities were connected with those of the coil of a delicate Galvanometer (q. v.). Had any trace of an electric current been produced, the needle of the galvanometer would have been deflected, but, when all disturbing causes were avoided, no such deflection was detected. Other experiments with a view to the detection of other physical energies, were also tried, but, like the first, with negative results only.

We must not hastily conclude that there is such a *thing* as force, though we are in the constant habit of speaking about it. Our sensations are all more or less misleading until we can interpret them. The pain produced by a blow is quite a different thing

from the energy of motion of a cudgel; and when our muscular sense impresses on us the idea that we are exerting force, we must be cautious in our conclusions. For it is certain that force is *merely the rate per unit of length at which energy is transferred or transformed.*

There are, in mechanics, several other quantities which retain a fixed value under certain circumstances. We may briefly consider a few of them.

Conservation of Areas. Invariable Plane.—We have seen (CENTRAL FORCES) that if a particle move about a center of force, its motion is confined to a plane, and its radius vector traces out equal areas in equal times. Similar theorems hold in any system of particles acted on only by their mutual attractions. If in such a system we suppose the positions of the respective particles to be continually projected (orthogonally, see PROJECTION) on any fixed plane, and radii vectores to be drawn from any point in that plane to the projections—the sum of the areas swept out by all those radii vectores will be equal in equal times. Also, this being true of all planes, there is one for which this sum is a maximum, and this plane is fixed in space. It is thence called the invariable plane of the system. Similar propositions hold for a system of bodies each of finite size, their several axial rotations being taken into account; hence what is called the invariable Plane (q. v.) of the Solar System.

Conservation of Momentum.—When two masses attract or impinge, the forces they exert on each other are evidently equal and opposite. Now, the measure of a force is the momentum it produces; hence equal and opposite momenta, in addition to their original quantities, will be communicated to the masses, and therefore the sum of the momenta of the two, resolved in any direction, will be unaltered; hence, *the sum of the momenta of any number of bodies will be unaltered by mutual actions either of the nature of attraction or impact.*

Conservation of the Motion of the Center of Gravity.—Again, in such a system, the momentum of the whole collected at its center of inertia, resolved in any assigned direction, is the sum of the momenta of the separate bodies in that direction; hence, *the center of inertia of a system, subject to none but the mutual actions of its components, either remains at rest, or moves uniformly in a straight line.*

For a simple, and as far as possible non-technical, discussion of the subjects so briefly noticed above, the reader may be referred to Tait's *Recent Advances in Physical Science* (second edition).

FORCE AND FEAR. As consent is of the essence, or rather is the essence of all contracts, and as consent implies not only intelligence, but unfettered power of action in the consenting parties, contracts, by the laws of all civilized nations, will be invalidated if it shall be proved that they were entered into under the influence of force or fear. Circumstances which constrain the will have the same effect as those which blind the understanding, and the law of force and fear is consequently closely analogous to that of Fraud (q. v.), including under that head misrepresentation, concealment, and consequent Error (q. v.). But it is not every degree of constraint, however exercised, which will have this effect in law. On the contrary, it must be of such a description as may be reasonably supposed to influence the will of the party in the circumstances in which he is placed at the time. In determining, therefore, whether there really has been force or fear in the legal sense, the law will take into account the age, sex, education, and other personal characteristics of the party, along with the accidental circumstances in which he was placed, e. g., the state of his health and spirits at the time, whether he was alone, what anxiety he may have felt for the life or interest of others, and the like. But 'where there is no peculiar weakness of age or sex, or condition,' says Mr. Bell, stating in this respect not the law of Scotland alone, but of most other countries, 'law will require, in order to annul a contract, such fear and compulsion as may reasonably shake a mind of ordinary constancy and resolution, and will not listen to the pretence of every vain and foolish fear.'—*Com. i. p. 22, Shaw's ed.* As a contract which is invalid on the ground of force and fear is not only incapable of being enforced after its invalidity has been ascertained by legal process, but from the absence of consent was invalid *ab initio*—i. e., no contract, in a legal sense, at all—the object of the law is to restore the parties to the position in which they were before it was entered into. All moneys which have been paid under the provisions of the extorted contract must consequently be repaid, and reparation in as far as possible must be made by the payment of damages for such personal injuries as the party who was dragged into it may have suffered from the enforcement of its provisions. See REDUCTION. By the law of England, Duress (q. v.) which will invalidate a contract must amount to fear of the loss of life or limb called Mayhem.

'Whatever is done by a man to save either life or member,' says Blackstone, 'is looked upon as done upon the highest necessity and compulsion. Therefore, if a man, through fear of death

or mayhem, is prevailed upon to execute a deed, or do any other legal act, these, though accompanied with all other the requisite solemnities, may be afterwards avoided.' But 'a fear of battery or being beaten, though never so well grounded, is no duress; neither is the fear of having one's house burned, or one's goods taken away and destroyed, because in these cases, should the threat be performed, a man may have satisfaction by recovering equivalent damages.'—*Stephen's Com. i. p. 142.* The avoidance of such a contract is, however, dependent on the will of the injured party. 'A contract made under duress may be avoided by the person whose free-will was thus restrained, though he has also an election, if he thinks proper, to insist upon it as a binding transaction' (*Ib. vol. ii. p. 62*). But the parties who are entitled to treat a contract either as a nullity or a subsisting contract, must make their election, and cannot, after treating the contract as rescinded, set it up as a subsisting contract (*Addison on Contracts, pp. 273, 436, and 1074*).

FORCELLINI, EGIDIO, an Italian philologist of great attainments, was born on the 26th of August 1688, in a village near Padua. Owing to the limited means of his family, F. was deprived of the benefit of early instruction, and was already verging towards manhood when enabled to commence a regular course of study in the seminary at Padua. His zealous industry, combined with unusual powers of learning, singled him out from his companions, and won the admiration of the learned principal, Giacomo Facciolati, who even associated him with some of his own scientific labors. The pupil rendered his teacher valuable service in the compilation of a highly important lexicon, a work which probably inspired both with the project on which F.'s literary repulse is based—viz., the compilation of a vast and comprehensive vocabulary of the Latin language. The work was published after F.'s death, and pronounced by public voice as one of the most valuable acquisitions to philological science of the age. In addition to the Italian and Greek signification of the Latin word, the literal and figurative application of each expression is given in a collection of examples, in themselves a perfect compendium of knowledge, embracing the customs, laws, arts, sciences, religion, and history of the Romans. This immense work was published in 4 vols., folio, under the title, *Totius Latinitatis Lexicon, consilio et cura Jac. Facciolati, opera et studio Aeg. Forcellini Lucubratum* (Padua, 1771). Furlanetto's appendix appeared in 1816 (Padua), and a new edition of the complete work was published in 1828 (Padua). F. died in 1768.

FORCENÉ, said, in Heraldry, of a horse when rearing, or standing on his hinder legs.

FORCEPS (Lat. a pair of tongs or pincers), the name given by surgeons to an instrument of great antiquity, used as a substitute for the fingers, and consisting of two levers of metal jointed together crosswise, nearer to one end than the other. The hand grasping the longer ends of the levers or handles, closes the shorter ends, which are shaped so as to seize firmly the intended object. There is scarcely a surgical operation in which it is not applied; and it is made of various forms, to suit different cases.

In addition to the forms used in Dentistry (q. v.), there is, e. g., the *dissecting* forceps, which has roughened points to lay hold of small portions of tissue which are to be divided by the knife; the *lithotomy* forceps, again, has blades concave like spoons; and *fenestrated* forceps have apertures in the blades, and as the soft tissues project into these, a firm hold is obtained with less risk of tearing the parts. By means of Liston's *cutting* forceps, a powerful hand can divide a great thickness of bone. But the most important of all is the *midwifery* forceps, an invaluable invention, in cases of difficult delivery, which daily rescues from suffering and danger numerous mothers and infants. It was gradually brought to its present perfection; but the name of Chamberlen, an accoucheur of the time of James II., is associated with it, as one of its chief improvers. It consists of two concave fenestrated blades, forming a cavity into which the head of the child fits. The blades are applied separately, one to each side of the head, and then locked together. Holding by the handles, the accoucheur aids the natural efforts of labor. The instrument does not necessarily or generally injure either mother or child.

FORCING, in Gardening, is the artificial application of heat to accelerate vegetation. The term is not usually applied to the cultivation of exotic plants in bothouses, where the object is to imitate as much as possible their native climate, but it is strictly applicable to the system usually pursued with vines and pine-apples, to secure the production of fruit at desired seasons and by different plants of the same kind in succession through a considerable period, the heat being increased for one set of plants sooner than for another. Many of the fruits and vegetables which grow well in the open air, are very commonly *forced*, in order that they may be procured at seasons when they could not without artificial means. Thus, sea-kale and rhubarb are forced by means of the heat produced by heaps of fermenting litter, by which at the same time they are blanched, and to this we

owe their appearance in the market very early in the season. Potatoes, pease, kidney-beans, asparagus, salads, &c., are often forced by means of hotbeds, or in flued pits; or a place is found for them in hothouses. Strawberries are cultivated in pots, and forced in hothouses; and some kinds of fruit trees are often treated in the same way, particularly cherries; and very diminutive trees may be seen richly loaded with fruit. Certain varieties are regarded by gardeners as particularly suitable for forcing. The system pursued in the Orchard-house (q. v.) cannot be called forcing.

FORD, FORDING. When a river or rivulet is crossed without the aid of either a bridge or ferry, it is said to be forded, and an established place for this crossing is called a ford. Thus, we have Oxford, Stratford, Deptford, Hungerford, &c., towns built around ancient fords. To the military engineer and the traveler in wild countries, the selection of the safest place for fording a river is a matter of some practical importance. In the first place, the widest part of the river should be chosen, as, wherever a certain quantity of water is flowing, the wider its bed—the rapidity of the flow being the same—the shallower it must be.

At the bend of a river, the line of shallow water does not run straight across, but extends from a promontory on one side to the nearest promontory on the other. The stream usually runs deep along hollow curves, and beneath steep perpendicular and overhanging banks, whilst it is always shoal in front of promontories, unless the promontory is formed by a jutting rock. For safe fording on foot, the depth of water should not exceed three feet; on horseback, four feet; or a foot less for each, if the current be very strong. The bottom of a ford should be firm and even; weeds, blocks of stone, &c., are serious obstacles, especially for cattle. When a caravan, a number of troops, or of cattle, have to cross, a sandy bottom is very bad, for the sand is stirred up and carried away by the stream, and renders the ford impracticable for the hindmost. For a small party, hard sand or gravel is the safest bottom.

The inhabitants of a district generally know the safest fords, and their experience affords a better guide than the best rules that can be given. Fords are continually varying, either from the swelling of the river or the shifting of its bed or banks, and therefore it does not follow that the place set down by one traveler as a safe ford, will continue so for the next that succeeds him.

FORD, JOHN, an English dramatist, was the second son of Thomas Ford of Ilington, in the county of Devon. The date of his birth is not known, but he was baptized in Ilington Church, 17th April 1586. His family was connected with the famous Lord Chief Justice Popham, and he became a member of the Middle Temple in November 1602; his cousin, a John Ford also, at the same period being a member of Gray's Inn. Unlike many members of the poetic tribe, F. seems to have adhered to his studies, and to have attained some professional success. His first poem was an elegy on the death of the Earl of Devonshire, entitled *Flume's Memorial*, and subsequently he assisted in the composition of various plays; perhaps from his conjunction with Webster and Decker, in this way, he acquired, or at least whetted, his appetite for tragic horrors. In 1629, he produced *The Lover's Melancholy*; and four years after, *The Broken Heart*, and *Love's Sacrifice*. Next year came *Perkin Warbeck*; and in 1638—1639, *The Fancies Chaste and Noble*, and *The Lady's Trial*. After this, F. drops out of literary history. Some think that he died soon after; others, that he retired to his native place, married, and lived to an old age, with sons and daughters growing up around him.

F. takes a high position as a dramatist, and this position he attains more by general mental force than by dramatic instinct, or by what we are accustomed to call poetic genius. In his compositions, there is a sense of effort; his writings look like task-work; and one can hardly suppose that he enjoyed his work. His versification—even when the subject matter is distinctly noble—is hard and prosaic. He has no humor. He has been praised for his pathos, but in his pathetic scenes effort is apparent. He cannot 'flatter' you to tears, as Shakspeare and the greater poets do. An edition of his works, published by Moxon (Lond. 1840), is enriched by biographical and critical notices by Hartley Coleridge; another, by the Rev. Alex. Dyce, appeared in 1869.

FORDUN, JOHN OF. Nothing more is certainly known of this early Scottish chronicler, than that he was a secular priest, and wrote about the year 1380. It has been inferred from his name that he was born at Fordun, in Kincardineshire, and it has been said that he was a canon of the cathedral church of Aberdeen. Having proposed to himself the compilation of a chronicle of Scotland, he is said to have traveled on foot through Britain and Ireland in search of materials. He lived to write only five books of his *Scotichronicon*, bringing the history down to the Death of King David I. in 1153. He left collections extending to the year 1385, about which time he is supposed to have died. The work which John of F. had left unfinished was resumed in the year 1441 by

Walter Bower, abbot of the monastery of Austin Canons Regular, at Inch Colm, or St. Colm's Inch, in the Firth of Forth. He enlarged the five books which F. had completed, and making use of his collections so far as they went, wrote eleven new books, bringing the *Scotichronicon* down to the year 1437; but he also made many arbitrary alterations which present things in quite a different light from Fordun's narrative. The work is the chief authority for the history of Scotland prior to the fifteenth century; its value being greatest during the fourteenth, when it is contemporary. It exists in upwards of twenty MSS., the principal of which is preserved in the Wolfenbüttel library. Four printed editions have been published, but the best is that edited by W. F. Skene (2 vols. Edinburgh, 1871—1872), from the text of the Wolfenbüttel and other standard MSS. Bower's interpolations and additions are separated from Fordun's text.

FORE (i. e., first), a term applied to the front or foremost part of a ship. The *forehold* is that part of the hold intervening between the cutwater and the foremast. The *forecastle* is that portion of the upper deck extending from the foremast to the bow; it is the part to which the common sailors have free access, and probably derives its name from a small turret or castle placed near the prow in ancient vessels, from which darts and other projectiles could be most conveniently hurled upon an enemy. *Foremast* is the first of the three masts, or of the two, when only that number are present. It is surmounted by the foretop-mast, foretopgallant-mast, and foreroyal; its sails being foresail, foretopsail, &c., between it and the bow flies the forestaysail, hoisted on the forestay, a massive rope passing from the foretop to the bow, and, with the backstays and shrouds, maintaining the mast in a perpendicular position. The *forebraces* are ropes passing from the extremities of the foreyard into the maintop, whence they descend through pulleys to the deck, where they serve, when necessary, to alter the direction presented by the foresail to the wind.

FORECLOSURE, in English Law, the process by which a mortgagor failing to repay the money lent on the security of an estate, is compelled to forfeit his right to redeem the estate. Every person having mortgaged his estate, is entitled to an equity of redemption, which can only be cut off by a formal process. For this purpose, the mortgagee files a bill of foreclosure, praying that an account may be taken of the principal and interest due under the mortgage, and that the mortgagor, on failing to pay, may forfeit his equity of redemption. If on the day fixed for payment, the money be not forthcoming, the mortgagor will be declared to have forfeited his equity of redemption, and the mortgagee will be allowed to retain the estate in perpetuity. See **MORTGAGE**.

FOREHAND RENT. In Scotch Law, rent is said to be forehand when it is made payable before the crop, of which it is the rent, has been reaped. After the period when it is due and exigible, forehand rent is *in bonis* of the lessor, and passes to his executor, not his heirs (Bell's *Law Dictionary*).

FOREIGN ATTACHMENT may have reference either to person or property. A defendant who has been arrested or attached in a foreign country, may be again arrested in England on the same ground of action. Thus, where a defendant had been arrested abroad on an English judgment, and escaped and came to England, the Court of Queen's Bench decided that he may be holden to bail in an action on the judgment. But after an arrest in Ireland or Scotland, the defendant cannot, in general, be again arrested in England for the same debt, neither of these countries being deemed foreign to that effect (Wharton's *Dic.*). Under the same name, a proceeding for securing the debts due to the defendant has been immemorially used in the cities of London and Bristol (Stephen's *Com.* iii. p. 663, *note*); and by the C. L. P. Act of 1854, a similar proceeding has been adopted, but with this difference, that whereas by a foreign attachment in the Lord Mayor's Court, debts are attached for the purpose of compelling the defendant to appear and put in bail to the action, no such proceeding can take place in the common-law courts till after judgment. See **GARNISHMENT**. In Scotland, where a creditor may both incarcerate a debtor and attach his effects, an English creditor may attach the property of his debtor, though he has imprisoned him in England. See **ATTACHMENT**, **APPREHEND**, **ARREST**, **FOREIGN COURTS**. The corresponding phrase in Scotland is *Arrestment*, which has reference both to person and goods, and is a proceeding at common law applicable to the whole country. As to the validity of a Scotch arrestment, *ad fundam jurisdictionem*, to enable the Scotch courts to proceed against a foreigner though absent, see the recent appeal case of the London and North Western Railway Co. v. Lindsay, Macqueen, iii. p. 99.

FOREIGN AUXILIARIES. In the early periods of English history, foreign auxiliaries were by no means uncommon. Harold had a body of Danes in his army when he defeated the Norwegian king; and to their refusal to march against the kindred Normans he owed not the least among the complications which ultimately overwhelmed him. Passing to modern times, William III. had

for some time a body of Dutch troops in his pay as king of England: throughout the 18th c., Hessian and Hanoverian regiments were constantly in the pay of the English government for temporary purposes. Hessians fought for us in the first American war; and the Landgrave of Hesse, who sold his troops at so much a head, received upwards of half a million for soldiers lost in the campaign. During the Irish rebellion, again, in 1798, many Hessian troops were employed.

On the outbreak of the continental war in 1793, it was determined to recruit the British army by the addition of a large body of foreigners; and accordingly, in 1794, an act passed for the embodiment of the 'King's German Legion,' consisting of 15,000 men. These troops, who were increased in the course of the war to nearly double that number, distinguished themselves in various engagements, and formed some of the regiments on which our generals could best rely. Corps of French *émigrés*, as the York Rangers and others, were also organized. The whole of the foreign legions were disbanded in 1815, the officers being placed on half-pay.

During the Russian war, in 1854, the British government again had recourse to the enlistment of foreigners; special provision being made in the act authorizing their employment, that the arms of the legionaries were in no case to be used against British subjects, in the event of internal discord. The numbers to be raised were 10,000 Germans, 5000 Swiss, and 5000 Italians; the pay to be the same as to British troops, but temporary service to convey no claim to half-pay. About half the number of men were enrolled, and were said to have reached great efficiency, when the stoppage of hostilities arrested their progress, and caused them to be disbanded at a great cost for gratuities, &c.

The Swiss auxiliaries used to form a regular contingent in many of the armies of Europe, especially of France and Italy. Over 1,000,000 served in France from the time of Louis XI. to that of Louis XIV. (1465—1715). See GARDES SUISSES. The Swiss usually served only on condition of being commanded by their own officers, and occasionally these officers obtained distinction and fame. But the privates returned home poor and often demoralized; and the cantons which supplied most mercenaries suffered severely by their absence. After the French Revolution, the cantons ceased publicly to hire out their subjects; and after 1830 most of the cantons forbade foreign enlistment. In 1859 the Confederacy passed a severe law against recruitment for service abroad. There is still, however, a large contingent of Swiss as mercenaries in the Dutch East Indian Colonies. The Papal Swiss troops have shrunk to a body-guard of about 100 men.

FOREIGN BILL OF EXCHANGE is a bill which is either both drawn and accepted abroad; or drawn by a person residing abroad on a person in this country, or the reverse. If a bill be drawn abroad, and accepted in England, it does not require a stamp; but if drawn in this country upon a correspondent abroad, or a foreign house, it must be stamped (19 and 20 Vict. c. 97, ss. 6 and 7); and when drawn abroad, it must be stamped by the holder, before he can present it for payment, or indorse, transfer, or otherwise negotiate it within the United Kingdom (Chitty on *Bills of Exchange*, 72). It has however, been decided that the stat. 17 and 18 Vict. c. 83, s. 3, does not render a stamp necessary where a bill drawn abroad has been indorsed abroad to a person in England, and presented by him for acceptance in England (Phillimore, *International Law*, iv. 609). Formerly, a bill drawn or payable in Scotland or Ireland, was foreign in England; but such bills were made inland by the statute just mentioned; and the same regulation was extended to the island of Man, Guernsey, Jersey, Alderney, and Sark (s. 7). See **BILL**. It has been established as a rule in England, that the liabilities of the drawer, the acceptor, and indorser, shall be governed by the laws of the countries in which the drawing, acceptance, and indorsement respectively took place (Phillimore's *International Law*, iv. p. 606 and 506).

In the case of bills which are both drawn and accepted abroad, and which are thus in reality foreign contracts, but of which the acceptor is a native of this country, and which are sought to be enforced in the courts either of England or Scotland, a distinction is made between the contract and the remedy: 'Whatever relates to the nature of the obligation—*ad valorem contractus*—is to be governed by the law of the country where it is made—the *lex loci*; whatever relates to the remedy, by suits to compel performance, or by action for a breach—*ad decisionem litis*—is governed by the *lex fori*—the law of the country to whose courts the application is made for performance or for damages.'—Lord Brougham in *Don v. Lippman*, House of Lords, 26th May 1837; Shaw and Maclean, ii. p. 723.

FOREIGN COURTS. Kent, after stating that in cases not governed by the constitution and laws of the United States, the doctrine of the English law, as to the force and effect to be given to foreign judgments, is the law of his own country also, observes, that the law thus common to England and America 'is exceedingly, if not peculiarly liberal, in the respect which it pays to

foreign judgments, in all other cases except the case of a foreign divorce or an English marriage. A distinction was early taken by Lord Nottingham, and is now recognized both in England and America, and indeed almost everywhere else, between a suit brought to enforce a foreign judgment, and a plea of a foreign judgment in bar of a fresh suit for the same cause. As the effect to be given to a foreign judgment is altogether a matter of comity, in cases where it has not been regulated by positive treaty, and no sovereign is bound to execute within his own dominions a sentence given out of it, the rule adopted, where a suit is brought to enforce a foreign judgment, is that the foreign judgment is to be received, in the first instance, as *prima facie* evidence of the debt, but that the defendant is entitled to impeach the justice of it, or to show that it was irregularly and unduly obtained. But the case is different where the losing party comes forward and wishes to institute a new suit upon the same matter, and to open up a foreign judgment dismissing the action, pronounced by a competent court. In this case, to interfere with the foreign judgment would be to assume the attitude of a court of review, and the rule in England, consequently, is that such a decision, when given by a foreign court, is final and conclusive. So obvious, indeed, is the convenience and necessity of this rule, that it has been regarded as forming a portion of general jurisprudence.'—Kent's *Com.* ii. 101, 102. As regards the enforcement of foreign decrees and judgments, the usages of nations have differed considerably, and the subject is far too wide and too difficult to admit of being satisfactorily discussed in this work. The distinction between the recognition of the judgment of a foreign court, as determining the validity of a foreign contract, and the application of a foreign remedy by the courts of this country, has been pointed out under **FOREIGN BILL OF EXCHANGE** (q. v.).

For practical purposes, however, it may be convenient that we should state that, contrary to the popular belief in England, the French courts are in the habit of giving effect to judgments obtained in England, and that debtors cannot escape from their creditors, as is too generally supposed, by simply crossing the Channel. The difficulty, no doubt, still exists where the debtor has escaped before any proceedings could be taken against him in this country, and where no judgment can be obtained. But if he has once been served with process in England, or cited either edictally or otherwise in Scotland, the creditor may go on with his action against him though he be personally absent from the country, and ultimately enforce his decree against him by the interposition of a French court. The same observations apply to Belgium. In England, there is no regular office, as in Scotland, for the publication of citations to persons abroad (see **EDICTAL CITATION**), but leave to substitute service at the last place of abode, in place of personal service, may now be obtained in some cases from the courts, or leave may be granted to serve out of the jurisdiction. In most countries, the rule as to two foreigners resident but not domiciled is, that they may sue each other in the ordinary courts, as natives do. To this the French courts are an exception, and hold themselves incompetent to entertain suits between undomiciled foreigners relating to personality, except in matters of commerce (Phillimore, *International Law*, iv. 645). See **JURISDICTION**; **DOMICILE**; **INTERNATIONAL LAW**, **PRIVATE**; **CONFLICT OF LAWS**, &c.

FOREIGN ENLISTMENT ACT. In the law of England, there was a statutory prohibition of enlistment in the service of a foreign prince in 3 Jac. I. c. 4, s. 18; but the statute commonly known as the Foreign Enlistment Act is 33 and 34 Vict. c. 90. It provides that if any British subject shall agree to enter the service of any foreign state, either as a soldier or a sailor, without the license of her majesty, or an order in council or royal proclamation, or if any person within the British dominions induces any other person to enlist in the service of a foreign state, such person shall be guilty of a misdemeanor. The officers of the customs, on information on oath, may detain any vessel having persons on board destined for unlicensed foreign service. Masters of vessels, knowingly having such persons on board, are punishable by fine or imprisonment, or both. Persons building any vessel for foreign service, without license, are guilty of a high misdemeanor, and the ship and stores are forfeited. Even to assist a foreign state with warlike stores, without license, is a misdemeanor punishable with fine and imprisonment. These penalties are irrespective of any consequences that may follow to the individual for having committed a breach of international law.

FOREIGNER. See **ALIEN**.

FO'RELAND, NORTH and SOUTH, two promontories on the east coast of Kent, between which are the Downs and Goodwin Sands. North F., the *Cantium* of Ptolemy, forms the north-east angle of the country and of Thanet Isle, in lat. 51° 22' N., and long. 1° 26' E., two miles east of Margate. It consists of chalky cliffs, nearly 200 feet high, projecting into the North Sea, and has a light-house with a fixed light, 184 feet high, and seen 24 miles off. South F., also composed of chalk-cliffs, is 16 miles south of

North F., 3 miles north-east of Dover in lat. $51^{\circ} 8' N.$, and $1^{\circ} 22' E.$ It has two fixed lights, respectively 380 and 275 feet above the sea, and seen from a distance of 25 and 22 miles. From this point, there is often a magnificent view of 200 to 300 merchantmen passing by, after having been detained by contrary winds in the Downs.

FO'RELOCK is a flat wedge driven through the end of a bolt to prevent its withdrawal: it is used principally on board ship.

FORESHORTENING, a term in Painting or Drawing, applied to signify that a figure, or a portion of a figure, which is intended to be viewed by the spectator directly or nearly in front, is so represented as to convey the notion of its being projected forward; and, though by mere comparative measurement occupying a much smaller space on the surface, yet to give the same idea of length or size as if it had been projected laterally. In compositions of figures and groups on ceilings, and in the interior of domes, &c., numerous examples will be found in which this art has been put in practice; in the works of Raphael, foreshortening is practised with most judgment and correctness; those of M. Angelo, Correggio, and Tintoretto display the greatest boldness; but the three last-named artists have been censured for introducing foreshortening too frequently into their compositions, for the purpose of parading their skill in practising it.

FOREST FLY (*Hippobosca equina*), an insect of the order *Diptera*. It receives the name F. F. from its frequent occurrence in forests, and particularly in the New Forest, Hampshire. It is also sometimes called **HORSE FLY**, from the annoyance which it gives to horses. It is a small insect, about four inches long; its wings, two in number, much exceeding the length of the abdomen. When at rest, the wings are laid flat on the back, one overlapping the other. The general color is brown, the thorax varied with pale yellow, the legs ringed with yellow and brown. The legs terminate in hooked claws. The skin is leathery and remarkably tough, so that the insect cannot be killed by any ordinary amount of squeezing. The structure of the mouth differs much from that of ordinary dipterous insects, and bears

Forest Fly (*Hippobosca equina*), magnified: 1, natural size; 2, the pupa, as deposited by the mother.

no inconsiderable resemblance to that of fleas. The F. F. lives by sucking the blood of quadrupeds, sometimes of oxen, dogs, &c., but most of all of horses. High-bred horses with smooth hair are most liable to this annoyance. The female F. F. does not deposit her eggs until they have reached the pupa stage in her abdomen. One only is produced at a time, enclosed in a tough, strong skin, egg-like, black, and shining like a bead, wonderfully large when the size of the abdomen from which it came is considered; the perfect insect finally emerges by bursting open a kind of lid or cap.

FOREST LAWS, in England, laws for the regulation of the royal forests. Forest is defined by Lord Coke to be a safe preserve for wild animals (*feræ*) of the chase, whence comes the term *foresta*, by the change of *e* into *o* (*Co. Litt.* 233 a). Both words probably spring from the same root as the Latin *foris* and the French *hors*, and signify that which is *without* the range of the peopled or cultivated country. Hence the Italian *forestiere* and *foresto*, and the Spanish *forestero*, signify strange, foreign, wild, and the like.

A forest, in the sense of the law of England, is a large tract of open ground, not necessarily covered with wood, but usually containing woodland interspersed with pasture, and forming part of the property of the monarch, and governed by a special code, called the forest law. This particular law had reference not only to matters connected with hunting and the like, but generally governed the persons living within the forest in all their relations. A chase is a smaller forest, in the hand of a subject, but not governed by forest law. Though the privilege of forest belongs of right to the sovereign alone, it may be granted by him in favor of a subject, who becomes entitled to exercise the privileges of forest in the district assigned. This right was exercised by the Saxon kings, who reserved large tracts of country for the royal pastime of hunting, and a charter of the forest was said to have been passed by Canute at Winchester in the year 1016. But the authenticity of this document is doubted by Lord Coke (*Inst.* iv. 320). William the Conqueror greatly extended the royal forests, by laying desert vast districts in Hampshire and Yorkshire; he also introduced penalties of the severest kind for offences against the game. The penalty for killing a stag or boar was loss of eyes; for William loved the great game as if he had been their father (*Sax. Chronicle*). It was not till the reign of Henry III. that the laws of the forest were reduced into a regular code. In the reign of that monarch was passed the charter of the forest, 9 Henry III.

(A.D. 1224). The right of the sovereign to create a forest is by the common law confined to lands of his own demesne. Henry II. had arbitrarily exercised his power by afforesting the lands of his subjects; but by the 1st and 3d chapters of the charter of the forest, it is provided that all forests so made should be disafforested. At a subsequent time, when Henry VIII. created Hampton Court Forest, he was obliged to obtain the consent of the freeholders, before he could erect a chase or forest over their grounds (*Coke Inst.* iv. 301). Mr. Hallam remarks: 'It is well known that Charles I. made Richmond Park by means of depriving many proprietors not only of their common rights, but of their freehold lands. It is not clear that they were ever compensated; but I think this probable, as the matter excited no great clamor in the Long Parliament.'—Hallam, *Const. Hist.* i. 463, note, 1st ed. By the charter of the forest, the penalties for destroying game are greatly modified. By cap. 10, it is provided that no man should lose life or limb for slaying deer, but that the punishment shall be restricted to fine or imprisonment for year and day. Cap. 11 contains the following curious privilege: 'Whatsoever archbishop, bishop, earl, or baron, coming to us at our commandment, passing by our forest, it shall be lawful for him to take and kill one or two of our deer by view of our forester if he be present; or else he shall cause one to blow an horn for him, that he seem not to steal our deer; and likewise they shall do returning from us.' This law is still unrepealed; so that a bishop may kill the Queen's deer, when summoned to or returning from parliament. Charles I. attempted to fill his empty exchequer by imposing penalties and exacting fines for alleged encroachments on the ancient boundaries of the forests, though the right to the lands thus taken was fortified by possession for several centuries.

This was one of the first grievances with which the Long Parliament dealt, and since the passing of the act for the 'certainty of forests' (16 Car. I. c. 16), the law of the forests have practically ceased. In Coke's time, there were sixty-nine royal forests, all of which, with the exception of the New Forest and Hampton Court Forest, had been created before the period of record. Of these, the principal were—the New Forest, Sherwood, Dean, Windsor, Epping, Dartmoor, Wichwood, in Oxfordshire, Saley Whittlebury, and Roekingham, in Northamptonshire, Waltham, in Lincolnshire, and Richmond, in Yorkshire. During the present reign, several of the royal forests have been disafforested by act of parliament—Hainault, 14 and 15 Vict. c. 43; Whittlewood, 16 and 17 Vict. c. 42; Wichwood, 19 and 20 Vict. c. 32. Public necessity is the plea on which these spots, long so famous for their silvan scenery, have been condemned. The plea is one which cannot be altogether disregarded; but it is to be hoped that it will not be suffered to prevail to the entire destruction of our royal forests, some of which, from their vicinity to large towns, afford resorts for public recreation highly prized by the citizens, and which never can be equalled in beauty and in healthfulness by any new-made pleasure-ground.

The royal forests of Scotland, in ancient times, seem to have been nearly as numerous as those of England. In Perthshire, there were the forests of Athole, Mamlorn, Glenartney, Glenfynlas, Glenalmond, Birnam, Cluny, Alyth, &c. In Forfarshire, there were Platan, Montrethmont, Kilgerry; in Kincardineshire, Cowie and Durris; in Aberdeenshire, the Stocket, Dyce, Kintore, Benachie, Drum, Birse, Braemar; in Banffshire, the Boyne and the Enzie; in Morayshire, Darnaway, &c. South of the Forth, there were the forests of the Torwood, Cadzow, Ettrick, Selkirk, Jedburgh, Traquair, the New Forest in Dumfriesshire, &c. The *Leges Forestarum*—the Scottish Forest Laws—have been printed more than once; the best edition is in *The Acts of the Parliaments of Scotland*, vol. i. pp. 323—328 (Edin. 1844). The forest code of Scotland, though neither so complete nor administered with the same rigor as that of England, was still generally complained of for its severe penalties or vexatious restraints. The grant of a right of forestry conferred the same privilege as if the ground over which it extended had been originally, and had continued to be, a king's forest. Hence arose great oppression and annoyance to neighboring proprietors, and in 1680 the supreme civil court suggested that a representation should be made to the king against the granting of new forests. From a case which was recently decided, it would seem that the high pretensions of royal foresters have in some places survived to the present day. The Dukes of Athole still hold the extensive mountainous district called the forest of Athole, either in their own right or as foresters for the crown. In virtue of his rights of forestry, the sixth duke claimed the power of preventing his neighbor, the Laird of Lude, from killing deer on his lands, and maintained that he was bound to allow the duke and his keepers to enter on his lands, and drive back any deer that might stray upon them from the forest of Athole. But the court decided against the duke on both points. See **DEER FORESTS**.

Forest Courts were courts established for the purpose of enforcing the forest laws in the royal forests. Of these courts, there were in England four—viz., the Court of Attachments, the Court

of Regard, the Court of Swainmote, and the Court of the Lord Justice in Eyre in the Forest, or Justice Seat. The last Court of Justice Seat that was held where business was transacted was in the reign of Charles I., before Lord Holland.

FOREST MARBLE, a member of the Lower Oolite, so called because of the occurrence of the typical beds in Wichwood Forest, Oxfordshire. The principal bed is a fissile limestone, containing large numbers of dark-colored shells, and capable of sustaining a fine polish. On this account, it is used to some extent as 'marble.' It is interstratified with blue marls and shale, and fine oolitic sandstones. The whole thickness of the group seldom exceeds forty feet.

FOREST OAK, a name sometimes given in commerce to the timber of *Casuarina torulosa*, and other species of *Casuarina* (q. v.), Australian trees. This timber, which is light yellowish brown, and prettily marked with short red veins, is imported into Britain, and used for ornamental work.

FORESTALLING. See **ENGROSSING**.

FORESTS. See **ARBORICULTURE**.

FORESTS, FOSSIL, have been frequently observed in the coal measures. The seams of coal having in general been formed from the vegetation of the locality where they occur, it is to be expected that when the coal is removed, the stools and roots of the trees would be observed in the immediately subjacent bed of shale—the

ancient soil. Such a forest was laid bare in an open work at Parkfield Colliery, near Wolverhampton, in 1844. In this case of about one-fourth of an acre, the stumps of 73 trees, with their roots attached, appeared as shown in the annexed ground-plan. The trunks, broken off close to the root, were lying prostrate in every direction, often crossing each other. One of them measured 15, another 30 feet in length, but they were generally shorter. They were invariably converted into coal, and fattened to the thickness of 1 or 2 inches.

Ground-plan of the Fossil Forest at Parkfield Colliery.

The upright stems show that some of them had a circumference of more than 8 feet. Similar fossil forest have been observed in the coal-fields of Nova Scotia, and have been carefully described by Lyell, Logan, and Dawson. The usual height of the trees observed by Lyell was from 6 to 8 feet; but one tree was about 25 feet high, and 4 feet in diameter. Brogniart describes the remains of a fossil forest preserved in an upright position, in strata of micaceous sandstone, belonging to the coal measures at St. Etienne, near Lyon. Though most abundant in strata of the carboniferous period, fossil forests have been observed in other formations. The Dirt-bed (q. v.) of the Lower Purbeck series is the remains of an ancient forest. Instances are also abundant in the pliocene strata.

Sometimes, as on the coast of Devonshire and on the shores of the Firth of Tay, they are exposed on the surface, stretching from high-water mark to far below the furthest limit of low water; or they are exhibited in section, as in the cliffs of Eastern Norfolk, where, resting on the chalk or crag, there is a stratum in which the stools and roots of the trees stand in their natural position, the trunks having been broken short off, and imbedded with their branches and leaves. This stratum is covered with fresh-water beds and drift. The position of these forests indicates a variation, in recent geological time, of the relative level of land and water. The instances in Devonshire and Fifeshire may imply a simple subsidence of the land; at Norwich, however, a considerable depression must have taken place, to admit of the deposition of the fresh-water beds and the till, and a subsequent elevation, to expose the beds so high above the sea-level.

The remains of ancient forests, belonging to a yet later period, are to be found in beds of peat. There is good evidence that some kinds of peat had their origin in the destruction of forests. Trunks and branches of beech, hazel, fir, &c., are found in them, and their roots may be traced in the underclay. The rapidity with which this peat is formed is very remarkable. At Blair Drummond, the stratum of peat is eight to ten, and in some places even twenty feet in thickness. Many of the trees here have been felled with the axe, and that this was done while the Romans were in possession of the country, is proved by the discovery of 'corduroy roads,' leading from one camp to another, and the finding of camp-kettles at the bottom of the peat.

FO'RFANG, or **FOREFANG** (Sax. *fore*, before, and *fangen*, to take), the taking of provisions from any one in fairs or markets, before the king's purveyors were served with the necessities for his majesty. (Charter of Henry I. to the hospital of St. Bartholomew in London, anno 1133, referred to in Toulmin's *Die*.) It is also used to signify the rescuing of stolen or strayed cattle from a

thief, or from those having illegal possession of them; or the reward fixed for such rescue (Wharton's *Die*).

FO'RFAR, supposed to be the ancient *Orrea*, the county town of Angus or Forfarshire, situated near a small lake of the same name, on a rising-ground in the fertile valley of Strathmore. Pop. (1871) 11,031; (1881) 12,818. It has been a royal burgh since the reign of King David I. (1124–1153). It had a royal castle, of which no vestige remains, said to have been situated on a round hill, on the north side of the town, and to have been destroyed by order of King Robert Bruce, in the year 1307. Its staple manufacture is linen. It is connected by railway with Aberdeen, Arbroath, and the south. It joins with Montrose, Arbroath, Brechin, and Bervie, in sending a representative to parliament.

FORFARSHIRE, or **ANGUS**, is a maritime county in the east of Scotland, being bounded on the E. by the German Ocean, on the N. by Kincardine and Aberdeen shires, on the W. by Perthshire, and on the S. by the Firth of Tay. It extends from north to south 38 miles, and from east to west 27 miles, with 45 miles of coast. There are several valleys of considerable extent, the principal of which are Glen Isla, Glen Prosen, Glen Esk, Clova, and Lethnot, which are all well watered, and mostly productive. The surface of the county is irregular, and it is intersected with hills, the Sidlaw being 1400 feet high, and Catlaw, the highest, 2264 feet. The soil, which is various, ranging from the finest alluvial to the moorish, rests mostly on the old red sandstone and the trap. Devonian paving-stones, limestone, porphyry, and jasper, occur. The chief rivers are the Tay, North Esk, South Esk, and Isla; and there are some small lochs. F. is the chief seat of the Scotch linen manufacture. Cattle, corn, salmon, and paving-stone are the principal exports. The climate partakes of the qualities common to the east coast. The average of the fall of rain is about 25 inches. The valued rent of the county in 1674 was £171,440 Scots, or £14,287 sterling. The valuation for 1880–1881 was £639,282 sterling, including £53,066 of railways. In 1881, according to the agricultural returns of Great Britain, the total acreage in the county of all kinds of crops, bare fallow, and grass, was 253,203; under corn crops, there were 94,104 acres; under green crops, 53,813; and of clover, sanfoin, and grasses under rotation there were 80,338. The total number of cattle returned for 1881 was 45,835; sheep, 119,386; pigs, 4964. The number of horses used solely for agriculture, &c., returned by occupiers of land in the same year, was 10,358. Pop. (1871) 237,567, which had, in 1881, increased to 266,374. The chief towns are Dundee, Arbroath, Montrose, Forfar (the county town), Brechin, and Kirriemuir. The county returns one member to parliament, and the boroughs two. Angus was the province of a *Mormaer* during the Celtic period of Scottish history. It appears as an earldom in the 12th century. Its first earls were probably the descendants of the old *Mormaers*; it passed subsequently to the Umphravilles, the Stewarts, and the Douglasses. The castle of Forfar was the residence occasionally of some of the kings, until the time of Alexander III. The chief antiquities are some Roman camps, the vitrified fort of Finhaven, the remarkable stone forts of the White Caterthun, near Brechin, and of the Laws, near Dundee; the sculptured stone pillars at Meikle, Aberlemno, St. Vigeans, Glamis, Kirriemuir, Aldbar, Invergowrie, &c.; the fortified island of St. Margaret's Inch in the Loch of Forfar, the round tower and cathedral of Brechin, the ruins of Restennet Priory and Arbroath Abbey; and the old baronial castles of Glamis, Red Castle, Edzell, Melgund, Finhaven, Airlie, Careston, Inverquhar. At Stracathro, it is said Baliol resigned the crown to Edward I. Several eminent men were born in this county—Hector Boece, Andrew Melville, the Marquis of Montrose, Joseph Hume, Sir Alexander Burnes, Robert Brown the botanist, James Mill the historian of British India; and Graham of Claverhouse had a seat at Finty Mains.

FORFEITURE AND CORRUPTION OF BLOOD are penalties consequent on convictions for treason or felony. The penalty of forfeiture for treason is founded on this consideration, that he who hath thus violated the first principles of government, and broken his part in the original contract between king and people, hath abandoned his connection with society, and hath no longer any right to those advantages which before belonged to him purely as a member of the community (Stephen's *Com. iv.* 497). The penalty of forfeiture for treason prevailed in England before the Conquest, as is clear from the fact, that lands held in gavelkind, which is a Saxon tenure, may be forfeited for treason. But after the Conquest, forfeiture of lands and goods came to be regarded as the peculiar punishment of felony, of which treason against the sovereign was the highest kind, and was denominated high treason, to distinguish it from all other felonies, which were called petty treason. In cases of treason, the offender forfeits all his lands absolutely to the crown. In felony, according to the old law, the offender forfeited to the crown the profits of all estates of freehold during his life, and all his estates in fee-simple for a year and a day, after which they became escheat to the lord.

The crown, during the year of occupancy, was entitled to commit upon the lands what Waste (q. v.) it pleased. By *Magna Charta*, this power of committing waste was restrained. But by 17 Ed. II. c. 16, the king's title to waste was again recognized. As the law now stands, murder is the only felony by which forfeiture for year and day is incurred. In all felonies, the goods and chattels of the offender are, on conviction, forfeited to the crown; but until conviction, forfeiture of the goods does not operate. Where, therefore, a person has disposed of his goods before conviction, the crown cannot reach them. Forfeiture of lands does not take effect until sentence of Attainder (q. v.) has been pronounced. So that a person committing *Felo de se* (q. v.), or a rebel dying before sentence, or killed in open rebellion, does not forfeit his lands. But sentence of attainder, as soon as pronounced, has a retro-active effect, and annuls all conveyances made between the act of treason or felony and the pronouncing of sentence. Conveyances made before the act of treason are not affected. Hence, a wife's jointure is not forfeited, because settled on her before the commission of the act. But dower is forfeited by 5 and 6 Ed. VI. c. 11. Counterfeiting the coin was formerly treason; but by various statutes, it is provided that the wife's dower should not be forfeited, and that the lands should be forfeited only for the life of the offender. Forfeiture for treason and felony is accompanied by *corruption of blood*, whereby the offender is incapable of inheriting any lands or of transmitting any title to an heir. But where the lands were not vested in the offender at the time of the act, they are not forfeited to the crown, but to the overlord.

In England, this distinction is of little moment, except in copyhold lands, the crown being, in fact, the overlord of nearly all the freehold land in the kingdom. By 7 Anne, c. 21, it was enacted that, after the death of the Pretender and his sons, no attainder for treason should operate to the prejudice of other than the offender himself; but this provision was repealed, 39 Geo. III., c. 93. But in Scotland, where subinfeudation still subsists, the distinction is of practical importance. In Scotland, before the Union, forfeiture of estate was incurred on account of treason and certain other crimes, as theft by a landed man, and uttering false coin. Lord Stair is of opinion that the doctrine of corruption of blood did not prevail in Scotland to exclude those claiming, through a person attainted, where the offender was only apparent heir (Stair, iii. 3. 38). Since the Union, the law of Scotland in regard to forfeiture for treason has been assimilated to that of England.

In America, forfeiture of estate for crimes is very much reduced, and the corruption of blood is universally abolished. Several of the state constitutions have provided that no attainder for treason or felony shall work corruption of blood or forfeiture of estate, except during the life of the offender, and some of them have taken away the power of forfeiture absolutely, without any such exemption. Every person convicted of any manner of treason, under the laws of New York, forfeits his goods and chattels, and also his land and tenements, during his lifetime; but the rights of all third persons existing at the time of the commission of the treason, are preserved. Kent's *Commentaries*, ii. 505.

FORFEITURE OF LANDS was originally a penalty of the feudal law, incurred on account of some act by the tenant inferring disloyalty to his overlord. The acts inferring forfeiture might be of either a civil or a criminal nature. Forfeiture for crimes was incurred by treason or felony. See **FORFEITURE AND CORRUPTION OF BLOOD**. Civil forfeiture may be incurred in England in three ways—viz., by tortious alienation, by wrongful disclaimer, and by alienation in mortmain; the first two of these modes were incidents of the feudal tenure, the latter was introduced by statute. It must be observed that, according to the earliest feudal customs, a gift of lands was always made in favor of a particular person, and that alienation, without consent of the overlord, involved a forfeiture of the fee. But this strictness having by degrees ceased to be observed, forfeiture was only incurred in case of a tortious alienation. Tortious alienation was where the owner of a particular estate conveyed by common law conveyance, as feoffment, fine, or recovery, a greater estate than that to which he was himself entitled, as where a tenant-for-life made a feoffment in fee. The immediate effect of this act was the forfeiture of the land to the remainder man or reversioner. By 3 and 4 Will. IV. c. 74, abolishing fines and recoveries, and 8 and 9 Vict. c. 106, s. 4, declaring that feoffment should not have a tortious operation, forfeiture by tortious alienation has ceased to have a practical importance.

Forfeiture by wrongful disclaimer was where a tenant holding under a superior lord, on being summoned in any court of record, either disclaims his allegiance, or does any act which amounts to a disclaimer. Since the abolition, by the statute of *quia emptores*, of subinfeudation, this species of forfeiture can only arise in lands held of the crown. Forfeiture by alienation in mortmain is incurred by the conveyance of lands or tenements in favor of any

Corporation (q. v.), sole or aggregate, ecclesiastical or temporal. As by vesting the land in a tenant of this description, the overlord was deprived of all the duties and services due by his vassal, this act was declared by various acts of parliament to infer the forfeiture of the lands. See **MORTMAIN**. Forfeiture of copyholds was incurred by committing waste, and by other acts of a wrongful kind inconsistent with the fealty due to the lord. See *Blackstone*, *Com.* ii. 284. Forfeiture on breach of condition, subsequent is where an estate is held upon a condition contained in the grant itself. On failure of the condition, the grantor or his heirs may enter upon the lands.

In Scotland, civil forfeiture may arise either from statutory enactment, at common law, or by agreement. By 1597 c. 246, it is enacted that vassals failing to pay their feu-duties for two years shall forfeit their right. This forfeiture must be established by an action to recover the feu-duties in arrear, and may be avoided by payment at the bar. At common law, a vassal forfeited his land by disclamation or purpresture. The former is analogous to the English disclaimer, and consists in the denial by a vassal of his lawful superior. Purpresture was incurred by the vassal's encroachment on the streets, highways, or commons belonging to the crown or other superior. These forms of forfeiture are fallen into disuse. Forfeiture on special agreement depends wholly upon the terms of the condition inserted in the titles to the land. The condition must be fortified by irritant and resolute clauses, and must enter the sasine, in order that it may be effectual against purchasers of the lands (*Erskine*, ii. 3, s. 13). Of this kind of forfeiture are breaches of Entails (q. v.).

FORGE, FORGING. The process of hammering red-hot iron or steel into any required shape is called Forging, and the workshop in which the operation is performed, a Forge. The principal tools of a common smith's forge are the fore-fire or hearth, with its bellows, the anvil, and the various hammers, swages, &c. For large work, an air-furnace, blown by steam bellows, supplies the place of the simple hearth of the blacksmith, powerful tranes swing the work to its place on the anvil, and a steam-hammer (see **HAMMER**) strikes the blows that squeeze the red-hot mass into shape. Besides these, there are portable forges of various sizes and forms, used for military and other purposes. They usually consist of an iron frame, to which a bellows, worked by the foot, is attached; and above the bellows is an iron tray, with a hearth, &c., upon which the fire is made; and the anvil is either attached to this frame, or has a separate stand.

Under **CUTLERY**, the general method of forging small work is described. For the largest work to which hand-hammers are still applied, such as anchor-forging, two gangs of from six to twelve hammermen are employed; they swing the large hammers with such wonderful precision and regularity, that the instant one hammer is withdrawn, another falls upon the same place. A foreman, with a wand, directs the hammering. The two gangs relieve each other alternately, on account of the great severity of the labor. Shovels, spades, mattocks, and many other tools and implements, are partly forged under the tilt-hammer. See **IRON**.

In all processes of forging, it is of primary importance to obtain the greatest possible rapidity in the succession of the blows. There is a double reason for this: first, and simply, that the work is cooling, and the more slowly it is forged, the more frequently it must be re-heated; and secondly, that percussion generates actual heat, and if the blows are sufficiently heavy and rapid, the temperature of the work may be fully maintained out of the fire for a considerable length of time. The hammer used for tilting steel not only maintains the heat of the bar, but raises it from a dull to a bright red heat.

FORGERY (Fr. *forger*, to form metal into shape, to fabricate), the *crimen falsi* of the Roman law, is held in England, at common law, to be the fraudulent making or altering of a writing or seal, to the prejudice of another man's right, or of a stamp to the prejudice of the revenue. As regards writings, the instrument forged must be executed with such skill or in such circumstances as to be capable of being mistaken for a genuine document by a person of ordinary intelligence and observation. It is not necessary that there should be even an attempt at imitation. If there was intention to deceive, and the circumstances were such as to render deception possible, the crime has been committed, and it has consequently been held in Scotland that it is possible to forge the name of a person who cannot write (1 Alison, p. 372), and further that the crime may be committed by the addition of a cross or mark (*Macmillan*, January 24, 1859). Any material alteration, however slight, is a forgery just as much as the subscription of the name of the pretended maker, or the fabrication of the entire deed. It will not lessen the crime, though the whole deed should be genuine, the name only being forged, or the name being really the handwriting of the party to whom it belongs, but appended to a forged deed. Even if the name be a fictitious one, but appended for the purpose of deceiving, a forgery has been committed just as much as if it belonged to a real person. Long

before the recent extensions took place in the law of evidence, by which parties were admitted as witnesses in their own causes. It was provided by 9 Geo. IV. c. 32, that the party whose name had been forged might be a witness to the effect that the writing was not his. But, on the other hand, it is an established rule of law that the proof of forgery, by a mere comparison of hand-writing, is incompetent (Tailor on *Evidence*, p. 1428, n. 5, 2d ed.).

Identification of handwriting is, if possible, more difficult than identification of the person, which so often forms the chief difficulty in criminal trials. 'As illness, strange dress, unusual attitude, and the like, cause mistakes in identifying the individual, so a bad pen, or rough paper, a shaking hand, hurry, and many other things, change the appearance of a person's handwriting.'—Dickson on *Evidence*, p. 474. There are besides resemblances in handwritings proceeding from many accidental causes, so that much caution is necessary in weighing this kind of evidence. 'It ought never, therefore, to be regarded as full proof by the crown in criminal trials, and even in civil cases, corroborative evidence should be required, unless the proof of handwriting is so clear as to shift the *onus probandi*.' Though writing-masters, engravers, bankers' clerks, and other persons in the habit of examining handwritings are often adduced as witnesses in trials for forgery, their evidence is really of very little value, and generally so conflicting that it can be produced with equal effect on either side. The best witness is one who has often seen the party write, through whose hands his writing has been continually passing, and whose opinion is not the result of an inspection made on a particular occasion for a special purpose. The act 11 Geo. IV., and 1 Will. IV. c. 66, makes the forging of the great seal, the privy seal, or any privy signet, the sign-manual, the seals of Scotland, or the great seal and privy seal of Ireland—treason. The same statute declares the offence of forging, or uttering with intent to defraud, stamps, exchequer bills, Bank of England notes, bills of exchange, promissory notes, deeds, receipts, orders for the payment of money, transfers of stock, wills, &c., to be felony. Capital punishment was first abolished with regard to special cases of forgery by 2 Geo. IV., and 1 Will. IV. c. 66, and 2 and 3 Will. IV. c. 123; and then altogether done away with by 7 Will. IV. and 1 Vict. c. 84. The offender is now liable to penal servitude, the length of which is at the discretion of the court; but which cannot be for less than three years, or he may be imprisoned for not more than four, or less than two years, with or without hard labor and solitude. As to the forgery of Bank of England notes, see 16 Vict. c. 2. As to obtaining property by false pretences, see FRAUD.

FORGET-ME-NOT, or **SCORPION GRASS** (*Myosotis*), a genus of annual or biennial herbaceous plants, of the natural order *Boraginæ*, with 5-cleft calyx and salver-shaped corolla; the flowers small, and generally blue. The genus is diffused over the temperate zone in all quarters of the world, and a number of species are common in Britain, chiefly growing in ditches and damp meadows—as *Myosotis palustris*, with crooked creeping perennial roots—an angular stem of a foot in height, and calyx covered with appressed bristles. *M. sylvestris*, with calyx covered with stiff spreading hairs, grows in bushy places and woods, and is often planted in flower-gardens. The dark blue *F.* of the Azores (*M. Azorica*) has of late begun to be cultivated in Europe, but requires the green-house. The genus is a favorite one with most persons, both because of the brilliancy of the flowers, and because throughout Europe it is generally regarded as the emblem of friendship.

The English name Scorpion Grass is now seldom heard. The German name *Vergissmeinnicht* corresponds with the English *Forget-me-not*.—*M. versicolor*, very common in Britain, often as a weed in gardens, is remarkable for the change of color in the flowers, which are first yellow then blue. They are very small.—*M. alpestris*, found on some of the mountains of Scotland, is especially admired for the size and brilliancy of its flowers.

FORIO, a thriving town of Italy, is picturesquely situated on the west coast of the island of Ischia, which stands at the northern side of the mouth of the Bay of Naples. The central portion of the town consists of very narrow streets, but the suburbs are composed of charming white cottages. It has three highly decorated churches, a good harbor, and some trade with Leghorn, Naples, and Genoa. Pop. 5791.

FORISFAMILIATION (literally, the putting forth from or beyond the family) is the separation of a child from the family of his father. A child is said to be forisfamiliar, either when he marries or when he receives from his father a separate stock, the profits of which are enjoyed by himself, though he may still reside with his father, or when he goes to live in another family with the consent of his father. The same result is also brought about when a child renounces his *legitim*, i. e., his legal share of the father's free movable property due to him on the death of the latter. See Bell's *Dic. of the Law of Scotland*.

FORKS. These table instruments are only about three centuries old. The Greeks, Romans, and other ancient nations knew nothing of forks. They had large forks for hay, and also iron forks for taking meat out of pots, but no instruments of the nature of table-forks. In ancient times, as is the practice still in the East, meat was commonly prepared as stews; or if roasted, it was cut into small pieces by a carver, so as to be easily taken in mouthfuls by the guests, who used their fingers and a knife for the purpose. It certainly is a strange fact, that the use of any species of forks at table was quite unknown till the 15th c., and they were then known only in Italy, which has the merit of this invention. None of the sovereigns of England had forks till after the reign of Henry VIII.; all, high and low, used their fingers. It was accordingly a part of the etiquette of the table to employ the fingers so delicately as not to dirty the hand to any serious degree; but as even by the best management the fingers were less or more soiled, it was the custom to wash the hands immediately on the dishes being removed from the table. Hence, in the royal household, there was a dignitary called the *Eurar* or *Euary*, who with a set of subordinates attended at meals with basins, water, and towels. The office of Euary survived after forks came partially into use. We learn that when James I. entertained the Spanish ambassador at dinner, very shortly after his accession, 'their majesties washed their hands with water from the same ewer, the towels being presented to the king by the lord treasurer, and to the queen by the lord high admiral.'

The Prince of Wales had a ewer to himself, which was after him used by the ambassador.—Ellis's *Letters*. The first royal personage in England who is known to have had a fork was Queen Elizabeth; but although several were presented to her, it remains doubtful whether she used them on ordinary occasions. From the inventory of her majesty's appointments in Nichols's *Progresses*, it would appear that these forks were more for ornament than use. 'Item, a knife and a spoune, and a forke of christall, garnished with golde slightly, and sparcks of garnetts: given by the Countess of Lyncolne. Item, a forke of corall, slightly garnished with golde: given by Mrs. Frances Drury. Item, one spoune and forke of golde; the forke garnished with two litle rubyes, two litle perles pendant, and a litle corall: given by the Countess of Warwick.' These ornamental forks had doubtless been presented to the queen as foreign curiosities of some value, and were probably never used at table. As yet, and for a considerable time afterwards, forks were not in common use, a circumstance less attributable to ignorance of the invention, than to prejudice. So far was this prejudice carried, by even educated persons, that one divine preached against the use of forks, as being an insult to Providence not to touch one's meat with one's fingers!

Italy, as has been said, claims the merit of this useful invention. This fact is explicitly learned from an account of a tour in Italy by a traveler named Thomas Coryate, who visited that country in 1608. His travels, styled *Crudities*, were published first in 1611, and republished in 1776. In these *Crudities* appear the following passages respecting the Italian towns: 'I observed a custom in all those Italian cities and townes through which I passed, that is not used in any other country that I saw in my travels; neither do I think that any other nation of Christendom doth use it, but only Italy. The Italian and also most strangers do always at their meals use a little forke when they cut their meat. For while with their knife, which they hold in one hand, they cut the meate out of the dish, they fasten the forke, which they hold in their other hand, upon the same dish; so that whatsoever he be that sitting in the company of others at meals, should unadvisedly touch the dish of meat with his fingers, from which all the table doe eat, he will give occasion of offence unto the company, as having transgressed the laws of good manners, in so much that for his error he shall be at the least browbeaten, if not reprehended in wordes. This form of feeding, I understand, is generally used in all places of Italy; their forks being for the most part made of yron, steele, and some of silver, but these are used only by gentlemen. The reason for this curiosity is, because the Italian cannot by any means indure to have his dish touched with fingers, seeing that all men's fingers are not alike cleane. Hereupon, I myself thought good to imitate the Italian fashion by this forked cutting of meate, not only while I was in Italy, but also in Germany, and oftentimes in England since I came home; being once quipped for that frequent using of my forke, by a certain learned gentleman, a familiar friend of mine, Mr. Laurence Whitaker, who in his merry humour, doubted not to call me at table *furcifer*, only for using a forke at feeding, but for no other cause.'

The term here employed jocularly, was in its serious meaning one of reproach, having been employed by the Romans to those slaves who as a punishment bore a forked frame or yoke (*furca*), resembling an inverted Λ —hence the Italian *forca* and *forchetta*; the latter (little fork) being followed in the French term *fourchette*, while the former is the root of the English word fork.

Forks came so slowly into use in England, that they were employed only by the higher classes at the middle of the 17th cen-

tury. About the period of the revolution, few noblemen had more than a dozen forks of silver, along with a few of iron or steel. At length, for general use, steel forks became an article of manufacture at Sheffield: at first, they had but two prongs, and it was only in later times that the three-pronged kind were made. As late as the early part of the 18th c., table-forks, and we may add knives, were kept on so meagre a scale by country inns in Scotland (and, perhaps, also in some parts of England), that it was customary for gentlemen in traveling to carry with them a portable knife and fork in a shagreen case; and till this day a small knife and fork form part of the ornamental equipment in the Highland dress. The general introduction of silver forks into Great Britain is quite recent; it can be dated no further back than the opening of the continent to English tourists at the termination of the French war in 1814. The extensive use of these costly instruments in the present day, marks in an extraordinary degree the rapid progress of wealth and refined taste throughout the United Kingdom.

FORLI, an interesting city of Italy, capital of the province of the same name, is beautifully situated at the foot of the Apennines, in a pleasant and fertile plain, on the right bank of the Montone, 16 miles south-west of Ravenna. It is a well-built, handsome city, is surrounded with walls, and contains many striking specimens of architecture, of which the Guerini Palazzo, built after the designs of Michael Angelo, the Palazzo Comunale, the Monte di Pietà, the cathedral, a majestic building, and the churches of S. Filippo Neri, of S. Girolamo, and of S. Mercuriale, are the most notable. The ecclesiastical buildings of F. contain some of the best pictures of Cignani, Carlo, Maratti, Guido, and other masters. The citadel, founded in 1361, is now used as a prison. The inhabitants carry on silk-spinning and salt-refining, with a considerable trade in corn, linen, hemp, carthamus, wool, &c. F. (the ancient *Forum Livii*) is said to have been founded by Marcus Livius Salinator, after his victory over Hasdrubal, on the Metaurus, 207 B.C., and to have received its name from him. In the middle ages, it formed a republic, and exchanged its rulers frequently during the struggles of the Guelphs and Ghibellines. In 1860, F., formerly in the States of the Church, became Italian. Pop. (1881) 16,016; of prov. 251,112.

FORLO'RN-HOPE, the body of men selected to attempt a breach, or to lead in scaling the wall of a fortress. Mr. Skeat derives the expression from the corresponding Dutch *de verloren hoop*, the word *hoop* (pron. as English *hope*) meaning a band or troop. The French is *enfants perdus*. The name is given on account of the extreme danger to which the leaders of a storming-party are necessarily exposed. As, however, the honor of success is proportionate to the peril of the undertaking, there is ordinarily no lack of volunteers for this arduous service.

FORMA PAUPERIS, the phrase usually employed both in England and Scotland to signify the arrangements by which an action may be carried on by one who is too poor to sue in the ordinary way. In England, the statutes 11 Henry VII. c. 12, and 23 Henry VIII. c. 15, provide that such as will swear themselves not worth £5, except their wearing apparel and the matter in question in the cause, shall be exempt when plaintiffs, but not when defendants, from the payment of court-fees, and shall be entitled to have counsel and attorney assigned to them by the court without fee. They are further excused from costs when unsuccessful; a privilege which, according to Blackstone, amounted in former times only to the rather uncomfortable alternative of choosing between paying and being whipped. In the event of success, however, a person suing in this form is entitled to his costs, because his counsel and agent, and the officers of court, though they are bound to give their labor gratis to him, are not bound to give it on the same terms to his antagonist, unless he too be a pauper. To prevent the abuse of suing in the superior courts at Westminster in this form in matters of small amount, it is provided (19 and 20 Vict. c. 108, s. 30), subject to certain exceptions, that any plaintiff who resorts to one of these, in a case falling within the cognizance of a county court, and recovers no more than £20, or in some cases £5, shall have no costs, unless he satisfies the court or a judge that he had sufficient reason for taking that course. There are some other exceptions to the rule (see Stephen's *Com.* iii. p. 646).

In Scotland, this benevolent arrangement was introduced by statute more than half a century before the date of the English act we have mentioned. In 1424, the statute (c. 45), which we have already quoted under *Advocates* (q. v.), was passed for the purpose of securing professional assistance, gratis, to the poor, and for giving to them and those who assisted them their costs in the event of success. The more special arrangements applicable to litigation in this form in Scotland will be detailed under *Poor's Roll* (q. v.).

FORMATION, in Geology, is applied to a group of strata united by some character which they have in common, whether of age, origin, or composition, as the coal or chalk formation.

FO'RMEDON, an old form of action, in the Law of England, whereby an heir of entail or remainder man who had been ousted by a discontinuance, was entitled to vindicate his claim to the lands from which he had been ousted. By 21 James I. c. 16, it was enacted that writ of formedon should be brought within twenty years of the time when the cause of action arose. Writ of formedon is now abolished, together with other real actions.

FO'RMIC ACID ($C_2H_3O_2, HO$) derives its name from the circumstance of its having been first obtained from the *Formica rufa*, or red ant. In a concentrated state it is a fuming liquor with an irritating odor, and occasions vesication if dropped upon the skin. It crystallizes at a temperature below 32° , and boils at about 212° , yielding a vapor which burns with a blue flame. It is a strong reducing agent, at a boiling temperature reducing the salts of silver, mercury, platinum, and gold.

It may be obtained in various ways, as, for example: 1. By the distillation of red ants with water (a proceeding never adopted now). 2. By the distillation of a mixture of starch, binoxide of manganese, sulphuric acid, and water; this is the usual method, and various organic matters, as sugar, chaff, bran, saw-dust, &c., may be substituted for the starch. 3. By the distillation of oxalic acid mixed with sand, or far better (according to Berthelot), with glycerine; 1 equivalent of oxalic acid ($C_2O_4, 2HO$) yielding 1 equivalent of formic acid ($C_2H_3O_2, HO$) + 2 equivalents of carbonic acid ($2CO_2$).

Berthelot has recently obtained it synthetically by keeping carbonic oxide gas for a prolonged period in contact with hydrate of potash, at a temperature of 212° . The gas becomes gradually absorbed, and formate of potash is the result, the reaction being exhibited by the formula, 1 equivalent of hydrate of potash (KO, HO) + 2 equivalents of carbonic oxide ($2CO$) = 1 equivalent of formate of potash ($KO, C_2H_3O_2$).

Formic acid is a very common product of the oxidation of organic bodies; thus, for example, the albuminates, glycine, sugar, starch, &c., yield it in association with other products, when acted on by chromic acid; the fats and fatty acids yield it when acted on by nitric acid; and it is a product of the action of ozone on glycerine, fats, fatty salts, acetic acid, and sugar, provided a free alkali is present. Hence, we can readily explain its occurrence as a product of oxidation in the animal organism, in which it not unfrequently occurs, either free or in combination. Thus we find it not only in ants, but in the poison of the bee and wasp, and in the hairs of the procession caterpillar. It has been detected by various chemists in the sweat, in the expressed juice of the spleen, pancreas, thymus gland, and muscles, in the brain, the blood, and the urine.

The salts of formic acid, which are termed by some chemists formates, and by others formiates, require no special notice. They are all soluble, and yield a red color with persalts of iron.

FORMI'CA. See *ANT*.

FORMING'S ISLAND is a speck on the bosom of the Pacific, lying a little to the north of the Sandwich Group, or Hawaiian Archipelago, in lat. $30^\circ 49' N.$, and long. $159^\circ 20' W.$ It is one of the most recent additions to the British empire, having been formally occupied, mainly on account of its excellent harbor, towards the close of 1860.

FORMO'SA (Chinese name, *Tai-wan*), a large island on the south-east coast of China, opposite the province of Fo-kien, from which it is distant about 90 miles. It lies between $21^\circ 53' - 25^\circ 16' N.$ lat., and $120^\circ 15' - 122^\circ 4' E.$ long. Length, about 237 miles; average breadth; about 70 miles. A chain of mountains nearly bisects the island, the eastern side of which is held by aboriginal savage tribes. These having massacred some shipwrecked Japanese sailors, were in 1874 attacked and punished by a Japanese force, which event nearly led to a war between China and Japan. The western side has been in possession of the Chinese since 1683, and is a department of the province of Fo-kien. Pop. from 2 to 3 millions. *Tai-wan-foo* (q. v.), the capital, and Takao on the west coast, and Tamsui and Keelung on the north, have been opened to foreign commerce by treaties. Coal abounds at Keelung and is largely shipped. Tea is extensively cultivated; other products are camphor, rice, maize, sugar, tobacco, cinnamon, pepper, &c.; oranges, pine-apples, guavas, cocoa-nuts, grapes, peaches, &c., are abundant.

FORMS OF ADDRESS. Many persons are exposed to inconvenience from their ignorance of the formal modes of addressing letters to persons of title; we shall therefore, in the present article, give an enumeration, taken mainly from Mr. Dod's *Peerage and Baronage*, of the usual ceremonious modes of written address. Previous to their employment, the writer must, of course, learn either from the peerage-writers, or from some other source, the precise rank of the person whom he wishes to address, as well as the hereditary, personal, or official distinctions by which the rank is often modified.

1. *Archbishop*—Letters are addressed: 'His Grace, the Lord

Archbishop of —, and commence: 'My Lord Archbishop.' More formal documents are addressed 'The Most Reverend Father in God (John Bird), by Divine Providence, Lord Archbishop of Canterbury; other archbishops and suffragan bishops being 'by Divine permission.' When personally referred to, an archbishop is styled 'Your Grace,' not 'Your Lordship.' The Archbishop of Armagh is addressed as 'His Grace the Lord Primate of Ireland.'

Archbishops' wives and the other members of their families, enjoy no titles, as such.

2. *Baron*—Addressed: 'The Right Honorable Lord —;' referred to as 'His Lordship,' or 'Your Lordship.'

Baron's Daughter—'The Honorable Mary —;' or, if married, 'The Honorable Mrs —.' Letters commence, 'Madam.'

Baron's Son—'The Honorable John —.' Letters commence, 'Sir.'

Baron's Son's Wife—'The Honorable Mrs. —.' Letters commence, 'Madam.'

Baron's Wife, and *Baroness* in her own right—'The Right Honorable Lady —;' in strictness, but more commonly, 'The Lady —.' Letters commence, 'Madam,' and refer to her as 'Your Ladyship.'

Baronet—'Sir John —, Bart.' Letters commence, 'Sir.'

Baronet's Wife—'Lady —.' Unless she has a title as the daughter of a peer, no Christian name is used. She is referred to as 'Your Ladyship.'

Bishop—'The Right Reverend the Lord Bishop of —.' Letters commence, 'My Lord.' Frequently the address is simply, 'The Lord Bishop of —.' The style in formal documents is, 'The Right Reverend Father in God (John —), by Divine permission, Lord Bishop of —.' Scotch bishops are addressed 'The Bishop of —,' sometimes as 'The Right Reverend Bishop (e. g., Henry Cotterell), and letters commence, 'Right Reverend Sir.' The colonial bishops are addressed by their territorial titles, like those of England.

Bishops' Wives and Children have no titles.

Countess—'The Right Honorable the Countess of —.' Letters commence, 'Madam,' and refer to her as 'Your Ladyship.'

Duchess—'Her Grace the Duchess of —.' Letters commence, 'Madam,' and refer to her as 'Your Grace.'

Duke—'His Grace the Duke of —.' Letters commence, 'My Lord Duke;' and he is referred to as 'Your Grace.'

Duke's Daughter—'The Right Honorable Lady Mary —,' or less formally, 'The Lady Mary —.' Letters commence, 'Madam,' and refer to her as 'Your Ladyship.' If she is married to a person of inferior rank, her surname only is changed.

Duke's Eldest Son—Uses the second or some other title of his family by courtesy, and he is addressed as if he held the title by law, though in formal documents he is called '—, Esq., commonly called the Marquis or Earl' (as the case may be).

Duke's Younger Son—'The Right Honorable Lord John Russell,' or less formally, 'The Lord John R—.' 'My Lord,' and 'Your Lordship.'

Duke's Younger Son's Wife—'The Lady John —,' unless where she has a title in her own right. 'Madam,' and 'Your Ladyship.'

Earl—'The Right Honorable the Earl of —,' or less formally, 'The Earl of —.' 'My Lord,' and 'Your Lordship.'

Earl's Daughter—Like Duke's Daughter (q. v.).

Earl's Eldest Son is addressed as if the title which he holds in courtesy were a title in law.

Earl's Younger Son—Like Baron's Son (q. v.).

Earl's Younger Son's Wife—Like Baron's son's wife, unless of superior rank to her husband.

Earl's Wife. See *Countess*.

KING—'The King's Most Excellent Majesty.' 'Sire,' and 'Your Majesty;' or, in less formal notes, thus: 'Mr. Pitt presents his duty to your Majesty.'

Knight Bachelor—Like Baronet (q. v.), except that the word 'Bart.' is omitted.

Knight Bachelor's Wife—Like Baronet's Wife (q. v.).

Knight of the Garter—K.G. is added to the name or other title of the bearer.

Knight of St. Patrick—K.P. used in the same manner.

Knight of the Thistle—K.T.

Knight of the Bath—if a Knight Grand Cross, K.G.C.B.; if a Knight Commander, K.C.B.

Knight of the Bath's Wife—Like the wife of a Baronet or Knight Bachelor.

Lord Advocate (of Scotland)—'The Right Honorable the Lord Advocate' by courtesy; but in official documents he is styled 'Her Majesty's Advocate for Scotland.' Letters ought strictly to commence, 'Sir,' not 'My Lord,' though the latter mode of address is the more usual.

Lord Lieutenant (of Ireland)—'His Excellency the Lord Lieutenant;' and letters commence in accordance with his rank in the peerage or otherwise. If a duke, he is styled 'His Grace the Lord Lieutenant.'

Lord Mayor—'The Right Honorable the Lord Mayor.' 'My Lord,' and 'Your Lordship.' There are only three Lord Mayors—those of London, York, and Dublin.

Lord Provost—The Provost of Edinburgh is 'The Right Honorable the Lord Provost;' of Glasgow, 'The Honorable the Lord Provost;' of Perth and of Aberdeen, 'The Lord Provost.' There are no other Lord Provosts. Perhaps the distinction in the title of the chief magistrate of the Scottish capital is traceable to his having been always a member of the Privy Council of Scotland, from at least the period of the Revolution.

Lord of Session (in Scotland)—'The Honorable Lord —.' 'My Lord,' and 'Your Lordship.'

Lords of Her Majesty's Treasury—These in their collective capacity are addressed as 'The Honorable the Lords Commissioners of Her Majesty's Treasury;' individually they have no title from their connection with the Treasury.

Maid of Honor—'The Honorable Miss;' and 'Madam.'

Marchioness—'The Most Honorable the Marchioness of —.' 'Madam,' and 'Your Ladyship.'

Marquis—'The Most Honorable the Marquis of —,' not 'The Most Noble.' Letters commence 'My Lord Marquis;' but when personally addressed, he is styled 'My Lord,' and 'Your Lordship.'

Marquis's Daughter—Like Duke's Daughter (q. v.).

Marquis's Eldest Son—Like Duke's Eldest Son (q. v.).

Marquis's Younger Son, like Duke's Younger Son (q. v.).

Mayors—In formal documents, 'The Right Worshipful the Mayor —;' but in letters, simply 'The Mayor.'

Members of Parliament—The letters M.P. are added to their usual address.

Officers in the Navy and Army—Their rank in the service, if above subalterns, is always prefixed to any other title they may possess, thus: 'Captain the Lord John —.'

Prince—'His Royal Highness Prince —;' or 'His Royal Highness the Duke of —,' when the Prince is also a Duke. In practice, the initials H.R.H. are usually substituted for the words. A letter begins 'Sir,' not 'My Lord Duke;' and the mode of reference is 'Your Royal Highness.'

Princess—'Her Royal Highness the Princess —,' or 'The Duchess' (as the case may be). 'Madam,' and 'Your Royal Highness.'

Prince's Wife, though of inferior rank, like a Princess by birth.

Privy Councillor—'The Right Honorable John —.'

Privy Councillor's Wife and Children have no title.

QUEEN—'The Queen's Most Excellent Majesty,' 'Madam,' and 'Your Majesty;' or, 'The Lord John R—' presents his duty to your Majesty.'

Viscount—'The Right Honorable Lord Viscount —,' or less formally, 'The Lord Viscount.' 'My Lord,' and 'Your Lordship.'

Viscountess—'The Right Honorable the Viscountess,' or less formally, 'The Viscountess.' 'Madam,' and 'Your Ladyship.'

Viscount's Daughter, like Baron's Daughter (q. v.).

Viscount's Son, like Baron's Son (q. v.).

Viscount's Son's Wife, like Baron's Son's Wife (q. v.).

The formality of these modes of address experiences considerable modifications when employed by persons of equal rank. Between friends and relatives they are either entirely dispensed with (except, of course, in addressing letters) or adapted to the feelings and caprices of the writers. In this, as in many other respects, we of the present generation are far less ceremonious than our fathers, and still less so than our grandfathers were. In most old letters, it will be found that the titles of the writers are preserved even where there is the freest and most familiar interchange of thought and feeling; wives addressing their husbands and husbands their wives, children their parents, and occasionally even parents their children, as 'Sir' or 'Madam,' 'My Lord,' or 'Your Royal Highness,' as the case might be.

FORMS OF PROCEDURE. See PROCESS.

FORNICATION (*fornicatio*, from *fornix*, an arch-vault, and by metonymy, a brothel, because brothels at Rome were in cellars and vaults under ground). In most countries, this crime has been brought within the pale of positive law at some period of their history, and prohibited by the imposition of penalties more or less severe; but it has always been found ultimately to be more expedient to trust to the restraints which public opinion impose on it in every community which is guided by the principles of morality and religion. In England, in 1650, during the ascendancy of the Puritan party, the repeated act of keeping a brothel or committing fornication was made felony without benefit of clergy on a second conviction. At the Restoration, when the crime of hypocrisy seemed for a time to be the only one which, under the influences of a very natural reaction, men were willing to recognize, this enactment was not renewed; and though notorious and open lewdness, when carried to the extent of exciting public scandal, con-

tinued, as it had been before, an indictable offence at common law, the mere act of fornication itself was abandoned 'to the feeble coercion of the spiritual court, according to the rules of the canon law, a law which has treated the offence of incontinence with a great deal of tenderness and lenity, owing perhaps to the constrained celibacy of its first compilers.'—*Blackstone*. The proceedings of the spiritual court were regulated by 27 Geo. III. c. 44, which enacts that the suit must be instituted within eight months, and that it cannot be maintained at all after the marriage of the parties offending. But proceedings in the ecclesiastical courts for this offence have now fallen into entire desuetude (*Stephen's Com.* iv. 347). In Scotland, shortly after the Reformation, fornication was prohibited by what Baron Hume calls 'an anxious statute of James VI.' (1567 c. 13), entitled 'Anent the Filthie Vice of Fornication, and Punishment of the same.' This act, which was passed in the same parliament by which incest and adultery are punished with death, provides that the offender, whether male or female, shall pay for the first offence a fine of £40 Scots, and shall stand bareheaded, and fastened at the market-place, for the space of two hours; for the second, shall pay a fine of 100 merks, have the head shaven, and shall be exposed in the same public manner; and for the third, pay a fine of £100, be thrice ducked in the foulest pool of the parish, and be banished the town or parish for ever. There is but one instance of this statute having been enforced by the Court of Justiciary, which occurs, as might be supposed, during the government of the Protector in Scotland. The offence of keeping a house of notorious ill-fame and scandalizing the neighborhood, is punishable in Scotland as a police offence, though it is greatly condoned. See NUISANCE and PROSTITUTES.

FORRES, a royal burgh in the county of Elgin or Morey, situated on a well-marked old sea-terrace and promontory distant about two miles from the mouth of the river Findhorn (q. v.). Pop. (1881) 4031. It was a royal burgh in the reign of King David I. (1124—1153), and was subsequently the seat of the Archdeacon of Moray, who had as his prebend the church of Forres, dedicated to St. Laurence the martyr, and the church of Logynfythenach (now Edinkillie), dedicated to St. John the Baptist. A painting of St. Laurence holding in his hand the gridiron on which he is said to have been roasted, is preserved at Brodie House near Forres. The antiquities of the place are the remains of its castle, at the west end of the town, now surmounted by a monument, erected to the memory of Dr. Thomson (a native of Cromarty, distinguished by his eminent medical services in the Crimean war), and the remarkable sculptured pillar—25 feet high—sometimes called Sueno's Stone, but more commonly 'the Stan'in' Stane,' which stands about a mile to the eastward. A monastery of black friars is said to have stood formerly on the site now occupied by Anderson's Academical Institution. F. lies at the foot of a curiously formed group of four gravelly hills, named the Cluny or Cleeny Hills, evidently water-made, on the highest of which, the site of an old encampment, is a tower 66 feet high, erected to the memory of Nelson in 1806. Upon one of these eminences is an excellent hydropathic establishment called Cluny Hill House.

FORSTER, JOHN, an English political and historical writer, was born at Newcastle in 1812. He was educated for the bar, but early, like so many other law-students, devoted himself to periodical writing. In this sphere of literature he displayed more than usual ability; and his political articles in the *London Examiner*, for which he commenced writing in 1834, attracted more attention than is usually bestowed on newspaper leaders. There was a vigor and point about them, coupled with a truth, consistency, and outspoken honesty, which obtained a wide renown for the paper. F. succeeded Dickens for a short time as editor of the *Daily News*, and was editor of the *Examiner* for ten years. He is the author of many admirable biographical and historical essays, and we are indebted to him for much new and valuable information tending to elucidate obscure points, and correct erroneous notions about the times and statesmen of the English Commonwealth. It is to this period of history that F. has chiefly directed his studies, and no person desirous of properly understanding it, should neglect his *History of the Grand Remonstrance; Arrest of the Five Members; Sir John Eliot, a Biography; and Lives of the Statesmen of the Commonwealth*. His literary memoirs are also excellent. The chief are *The Life and Times of Oliver Goldsmith* (1848); *Walter Savage Landor*, 2 vols. (1868); *The Life of Charles Dickens*, 3 vols. (1871—1874); and the first volume of a *Life of Swift* (1876). F.'s style is clear, forcible, and elegant. He was appointed Secretary to the Commissioners in Lunacy in 1856, and a Commissioner in Lunacy in 1861. F. died in 1876.

FORSTER, JOHANN REINHOLD, a German traveler and naturalist, was born in Dirschau, in Prussia, in 1729, and died in Halle in 1798. He was educated at Halle and Danzig for the clerical profession, and in 1753 became pastor at Nassenhuben, near Danzig; but he seems to have devoted most of his time to

the study of mathematics, natural philosophy, natural history, and geography. In 1765, he accepted an offer made to him by the Russian government, to inspect and report upon the new colonies founded on the banks of the Volga; and the matter of his report is said to have been so good as to have given the Empress Catharine suggestions for her great code of laws. His irritable temper soon involved him in difficulties with the Russian government; and in the following year he repaired to England, where the exertions of some of his scientific friends in London soon procured for him the office of teacher of natural history, and of the French and German languages, at an educational institution for dissenting elergymen at Warrington, in Lancashire. He retained this post until 1772, when he received, through the influence of Mr. Banks, the offer of naturalist to Captain Cook's second expedition to the South Seas. In the course of the voyage, his temper seems to have frequently brought him into unpleasant collision with the other officers; and after the return of Captain Cook's vessels in July 1774, a controversy arose between F. and Lord Sandwich, on the question as to who should write the narrative of the voyage. It was settled that F. should write the philosophical and Cook the nautical parts of the work; but further difficulties arose, and Cook's journal appeared alone. In 1776, in association with his son, he published a work (in Latin) on the botany of the expedition; and in 1778 his *Observations faites dans un Voyage autour du Monde sur la Géographie Physique l'Histoire Naturelle, et la Philosophie Morale*. In the latter year, he returned to Germany, and was soon afterwards made Professor of Natural History and Mineralogy at Halle, where he remained until his death. Besides the above works, he published *De Byssu Antiquorum* 1775; *Zoologia Indica*, 1781; *Geschichte der Entdeckungen und Schiff-fahrten im Norden*, 1784 (Eng. and French trans.), &c.

FORSTER, JOHANN GEORG ADAM, commonly known as George F., eldest son of Johann Reinhold Forster (q. v.), a German traveler and naturalist, was born at Nassenhuben, near Danzig, in 1754, and died at Paris in 1794. When only 17 years of age, he accompanied his father in Captain Cook's second voyage; and shortly after his return, he published, with the assistance of his father, an account of the expedition. His book, which does not differ materially in its facts from Cook's narrative, was well received by the public, and was translated into French, German, Swedish, and other languages. Humboldt spoke of this work in the highest terms. F., for a time Professor of Natural History at Cassel and at Wiina, was librarian to the Elector when Mainz was taken by the French in 1792. F., who had become an ardent republican, was sent as a deputy to Paris, to request the incorporation of Mainz with the French republic.

While he was in Paris on this mission, the Prussians retook the city, and F. lost all his property, including his books and manuscripts. He died 12th January 1794. Besides numerous translations, and the account of Captain Cook's voyage, he wrote a number of minor works. His widow, the daughter of Heyne (Therese Huber), published his *Letters* in 1828; and a complete edition of his works, in 9 vols., was published in 1843.

FORSTER, THE RIGHT HON. WILLIAM EDWARD, son of William Forster, who was for more than 50 years a minister of the Society of Friends, and died on an anti-slavery mission in Tennessee, was born at Bradpole, Dorset, on July 11, 1818. He was educated at the Friends' School, Tottenham, and became a worsted manufacturer at Bradford. In 1846 he distributed in Ireland a famine relief fund raised by the quakers. In 1859, he contested Leeds unsuccessfully in the Liberal interest, and in 1861 was elected for Bradford. He filled the post of Under-Secretary for the Colonies from November 1863 till July 1866, and was Vice-president of the Committee of Council on Education, and Fourth Charity Commissioner, from 1868 to 1874. Mr. F. acquired a great reputation from the admirable manner in which he piloted through the House of Commons the Education Bill of 1870, and also the Ballot Bill of 1871. He became Irish Secretary in the Liberal Ministry of 1880. The extent to which outrage and intimidation prevailed in Ireland led the government to pass, in the face of the opposition of the Irish party, a Peace Preservation or Coercion Act, giving the Irish administration the power of imprisoning without trial persons reasonably suspected of crime; and on F. was concentrated all the odium of introducing and applying this measure. When, in 1881, the leaders of the Land League were arrested, the bitterness with which 'Buckshot Forster' was denounced throughout Ireland was prodigious; though F. deserved great credit for zeal, determination, and skill in carrying the Land Act of 1881, which conferred unparalleled privileges on the Irish tenantry. In May 1882 the government resolved to release the chief political suspects; and Mr. F., disapproving this step, resigned office.

FORT, a term of peculiar meaning in British N. America, applied to a trading-post in the wilderness with reference to its indispensable defences, however slight, against the surrounding bar-

barism. It has thus been often employed to designate merely a palisaded log-hut, the central oasis of civilization in a desert larger, it may be, than Scotland.

FORT, FORTRESS (from Lat. *fortis*, strong), a stronghold, made secure by walls, and generally further protected by a ditch and parapet. For the construction of forts, see **FORTIFICATION**.

FORT ADJUTANT, an officer holding an appointment in a fortress—where the garrison is often composed of drafts from different corps—analogueous to that of adjutant in a regiment. He is responsible to the commandant for the internal discipline, and the appropriation of the necessary duties to particular corps. Fort adjutants are staff-officers, and so receive a certain allowance per day in addition to their ordinary regimental pay.

FORT AUGUSTUS, a village at the S. end of Loch Ness, 29 miles S.W. of Inverness. A fort intended to overawe the Highlands, and having accommodation for 200–300 men, was built here soon after the rebellion of 1715, on a small eminence. It was taken by the rebels in 1745, and became the headquarters of the Duke of Cumberland after Culloden. In 1867 the fort and crown property adjoining were sold to Lord Lovat, who has since converted it into a Benedictine Educational Institute.

FORT GA'RRY, a Hudson's Bay Company's station, beside which has sprung up the thriving town of WINNIPEG, capital of the province of Manitoba, in the Dominion of Canada. Winnipeg (q. v.) is situated at the junction of the Assiniboine and Red Rivers. Pop. (1871) about 350; (1881) 15,000.

FORT GEORGE, a fortification in the N.E. of Inverness-shire, on a low sandy projection into the Moray Firth, here only 1 m. broad. It is the most complete fort in the kingdom, and was built, at a cost of £160,000, after the rebellion of 1745, to keep the Highlanders in subjection. It covers 12 acres, and can accommodate 2000 men. It is an irregular polygon, with 6 bastions, and upwards of 70 guns. It is defended by a ditch, covert-way, a glacis, two lunettes, and a ravelin. It has casemated curtains, 27 bomb-proof rooms, bomb-proof magazines, and is supplied with water from 8 pump-wells. It is, however, only secure from attack by sea.

FORT GEORGE (INDIA). See **MADRAS**.

FORT MAJOR, the next officer to the governor or commandant in a fortress. He is expected to understand the theory of its defences and works, and is responsible that the walls are at all times in repair. He is on the staff, but has to resign his regimental appointment, and receives an addition to his half-pay.

FORT ROYAL, a fortified seaport of the French island of Martinique, in the West Indies, is the capital of the colony. It stands on the west coast, in a bay of its own name, in lat. 14° 35' N., and long. 61° 4' W. It has a population of about 12,000, and contains offices for the local government, barracks, arsenal, and hospital.

FORT ST. DAVID, on coast of the Madras province, in the district of South Arcot, 100 miles south of Madras. It became British in 1691, and was an important place during the struggle of England with France. It was the capital of the English settlements in the Carnatic from 1746 to 1758. It soon decayed.

FORT WAYNE, a city of Indiana, U.S., on the Wabash and Erie Canal. It is a railway center, has machine shops, flour-mills, tanneries, and other manufactures. Incorporated in 1840, it had 17,718 inhabitants in 1871, and 26,881 in 1881.

FORT WILLIAM, a village in Inverness-shire, near the west base of Ben Nevis, 63 miles south-west of Inverness, and at the south end of the Caledonian Canal. A fort was originally built here by General Monk, and afterwards rebuilt on a smaller scale by William III. It is an irregular work, with ditch, glacis, ravelin, bomb-proof magazine, and barracks for 100 men. It resisted sieges by the Highlanders in 1715 and 1745. It is now converted into private houses. F. W., so long one of the keys of the Highlands, is now, like Oban, only a center for tourists. Pop. (1881) 1594.

FORT WILLIAM (INDIA). See **CALCUTTA**.

FORTÉ, in Music, the Italian term for loud; *fortissimo*, as loud as possible.

FORTESCUE, SIR JOHN, an eminent judge and writer on English law, descended from a Devonshire family, was the son of Sir Henry Fortescue, Lord Chief-justice of Ireland, and was born some time in the reign of Henry IV. Educated at Exeter College, Oxford, he was called to the bar at Lincoln's Inn, and in 1441 was made serjeant-at-law. The following year, he was appointed Lord Chief-justice of the Court of King's Bench. In the struggle for the crown between the Houses of York and Lancaster, he steadily adhered to the latter, and is supposed to have been for a time Lord High Chancellor of England. Lord Campbell in his *Lives of the Lord Chancellors* (vol. i. p. 367), under date Feb-

ruary 17, 1461, says: 'If Sir John Fortescue ever was *de facto* chancellor, and in the exercise of the duties of the office, it must have been now, after the second battle of St. Albans, and at the very conclusion of the reign of Henry VI.' In March of that year, he fought at the battle of Towton for that Monarch, and was attainted by the parliament under Edward IV. He accompanied the Queen, Margaret of Anjou, and her young son, Prince Edward, on their flight into Scotland, and while there wrote a treatise in support of the claim of the House of Lancaster to the English crown. In 1463, he embarked with the queen and her son for Holland, where he remained for several years, intrusted with the education of the young prince. During his exile, he wrote his celebrated work, *De Laudibus Legum Anglie*, for the instruction of his royal pupil. In the introduction and throughout the dialogue, he designates himself 'Cancellarius.' It was when he was in Scotland that the title of Chancellor of England is said by some to have been conferred upon him by the dethroned monarch. He probably had the titular office of chancellor *in partibus* during his exile, but never exercised the functions in England. In 1471, he returned with Queen Margaret and her son; but on the final defeat of the Lancastrian party at the battle of Tewkesbury, where he is said to have been taken prisoner, finding that parliament and the nation had recognized the title of Edward IV., he submitted to that monarch, and, as a condition of his pardon, wrote a treatise in favor of the claim of the House of York. He was allowed to retire to his seat of Ebrington, in Gloucestershire, where he died in his 90th year. His male representative was, in 1789, created Earl Fortescue and Viscount Ebrington in the peerage of Great Britain.

FORTH, a river of Scotland, rises in the northwest of Stirling-shire, in the mountains between Loch Katrine and Loch Lomond, from two main branches, the Duchray, 16 miles long, from the east side of Ben Lomond, and the Avendhu, 12 miles long, flowing through Lochs Chon, Dhu, and Ard. These streams unite at Aberfoyle, and issue from the mountains. The F. then runs east and south-east along the borders of Perth and Stirling shires, with numerous windings, in a wide valley abounding in picturesque scenery. It passes Stirling, and a little above Alloa it widens out into the Firth of Forth. The F. is only 50 miles in a straight line from its source to the mouth of the Devon; but, owing to its sinuosities, its real course is more than twice that length. It is navigable for vessels of 100 tons to Stirling. Its chief tributaries are the Teith, the Allan and the Devon.

FORTH, FIRTH OF, an arm of the sea, or the estuary of the river Forth, lies between Clackmannan, Perth, and Fife on the north, and Stirling and the Lothians on the south. It first extends six miles south-east from where the Devon joins the Forth; then, with an average breadth of 2½ miles, it runs 10 miles to Queensferry; and finally, it extends 36 miles north-east, gradually expanding in width to 15 miles between Fife-ness and Tantallon Castle on the coast of Haddingtonshire. The project of building a railway bridge across the estuary at Queensferry was resumed in 1881; at Alloa also a bridge is to be made. The waters of the Firth are from 7 to 30 fathoms deep, and encircle the Isle of May, Bass Rock, Inchkeith, Inchcolm, Cramond Isle, &c. On the coast, are many fine harbors. St. Margaret's Hope, above Queensferry, is one of the safest roadsteads in the kingdom. The chief rivers which fall into the firth are the Forth, Carron, Avon, Almond, Esk, and Leven. The counties along its shore are the most fertile and best cultivated in Scotland, and include the maritime towns of North Berwick, Musselburgh, Portobello, Leith, Queensferry, Grangemouth, Culross, Burntisland, Kirkcaldy, &c.

FORTHCOMING, in the Law of Scotland, is an action by which an arrestment is made available to the arrestor. The arrestment secures the goods or debts in the hands of the creditor or holder; by the forthcoming the arrestee and common debtor are called before the judge to hear sentence given, ordering the debt to be paid, or the effects to be delivered up to the arresting creditor. (Bell's *Law Dictionary*.)

FORTIFICATION, a term derived through the Italian from the Latin *fortis* and *facere*, means literally the 'making strong' of any place whatever, be it a town, an arsenal, a camp, a mere house, or the extended position of an army occupying a tract of country, a province, or even a kingdom. In effect, the term is limited to strengthening by means of walls, ditches, or other stationary obstructions, aided more or less by artillery, which may impede hostile advance.

Fortification cannot pretend to render strongholds impregnable, for no works, however skillfully devised, will withstand the continued fire of well-directed artillery, backed by energy and discretion on the part of assailants: its aim is to enable a beleaguered garrison to hold out, without losing ground, until it can be relieved by the advance of allies operating in the field. In fortifying a place, the engineer usually proceeds upon some defined system of entourage; but if he hope for success, his science must be sufficiently elastic to adapt itself to all the natural features of

the locality; and from this it follows that a system perfect in theory, and of universal application, will in practice have to undergo modifications, differing in almost every instance.

The origin of the art is involved in an obscurity which history need not hope to penetrate. The earliest records of all nations speak of walled cities and forts.

The prime element of all fortification is the parapet (from Italian *para*, before; *petto*, the breast), which may be a wooden stockade, a wall of masonry, or a mound of earth, and is intended to give more or less cover to the defender from the projectiles of his adversary, while he is still able to use his own weapons against the latter. The simplest form of parapet being the mound of earth, the ground adjoining it would probably be dug up for its formation, and from this would almost unconsciously ensue the ditch, as an additional means of separating the assailant and the assailed. Starting, then, from this parapet and ditch or fosse, as the elementary forms of defence, it will be well, before proceeding to describe the ancient and modern systems, to give concise practical definitions of the parts, adjuncts, and technical names of a fortification.

The first duty of a defender is to prevent, as far as possible, the enemy's near approach to any of his works. In developed systems, this is sought to be done by bastions, &c. (of which hereafter), which stand out at angles to the general line, so as to afford a fire commanding all parts. But as cases occasionally happen of troops, defended by a mere straight parapet and ditch, having to withstand the advance of the enemy, it is necessary to adopt every measure which can obstruct his path, harass his advance, and, if possible, aid in cutting off his retreat in the event of failure.

Abattis (q. v.) are among the simplest obstacles to be improvised, consisting of trees cut down, shorn of their leaves and smaller twigs, having their branches pointed, and then laid close together, in one or more lines parallel to the works, branches outward, and trunks imbedded or pinned down in the earth. Accoutred troops must remove these before they can pass, and the operation of removal under fire from the besieged is a very serious one indeed.

Chevaux-de-frise (q. v. for derivation and illustration) are pointed iron or wooden rods fixed crosswise in a wooden beam, and until removed offering a complete obstacle to progress. They are very useful in a breach or other enclosed portion of a work, and are now made in pieces, so as to be portable, and yet ready for immediate putting together. A *cheval-de-frise* is usually 12 feet long, with a beam 9 inches square.

Chausse-trapes, or *Caltraps* (q. v.), give serious annoyance to troops advancing, and are especially dangerous in cases of night-attack. Their use was, however, more general formerly than it is now.

Trous-de-loup (wolf-traps), which are deep holes dug, and armed at the bottom with spikes, young trees cut down and their stumps pointed, inverted harrows, broken sword-blades, bayonets, or any similar annoyances, are resorted to as expedients to gain time, and thereby insure a more deadly fire on the assailants. They are frequently constructed in the glacis of a work.

Fraises and Stockades represent another form of additional de-

Fig. 1.—Fraise and Stockade (in section):
AB, parapet; C, escarp; D, fraise; E, stockade; F, glacis;
G, ditch; H, counterscarp.

fence, and are stout posts driven horizontally or perpendicularly into the earth, in long close rows. Fig. 1 shows the use of both these defences in the ditch of a fortress, and it will be perceived

Fig. 2.—Stockade.

Fig. 3.—Double Stockade.

at once how formidable to an attacking party solid lines of these posts must be. The stockade forms likewise, at times, a good substitute for the parapet itself, particularly when the direct fire

of artillery is unlikely to be brought against it, as in warfare with barbarous tribes, or in a work at the very crest of a steep hill. In this case it is usually constructed of two rows of strong palisades firmly imbedded in the ground: the outer nearly a foot square, planted with three-inch intervals between; the second about six inches in diameter, closing these spaces behind. Every second small palisade is cut short a few inches, so as to leave a loophole for musketry-fire (as in fig. 2). A hill protected in this manner is shown in fig. 3.

CONSTRUCTION OF THE PARAPET.—The object of the parapet being to defend, or *degrade* a certain portion of ground behind it, its height must be calculated so that missiles passing across its crest shall fail to strike the troops mustered behind. The mini-

Fig. 4.

mum width defiladed to allow of safe communication for troops behind, and actually defending, is 30 feet; but if the men have to be drawn up in line, not less than 90 feet will suffice. The mode of ascertaining the height of parapet necessary in particular cases will be seen from the next diagram (fig. 4). Let A be the position at which the parapet is to be made, and AB the space which it is required to defilade to a height throughout equal to BC. D, D₁, D₂, are three points, according to the supposed country round, from which fire could be had at the parapet—one, D, being on the level, the others on the ground respectively higher and lower than the parapet: if lines be now drawn from these points to C, their intersection with a perpendicular, raised on the point A, will show the elevation necessary for the parapet protecting the space AB to the height BC. From this, the disadvantage will be apparent of constructing a parapet within range of higher ground, as for every extra foot of elevation in the commanding rise a proportionate addition must be made to the height of the parapet.

In practice, the ordinary parapet for a level is eight feet high, which allows for the depressed trajectory of a spending ball. See **PROJECTILES**. If the parapet be raised on ground above the attacking position, it may be lowered, according to the angle, to about six feet six inches, the height necessary for a man standing up to be thoroughly protected. On the other hand, if the position, A, be lower than the point occupied by the assailant, the parapet must be raised; as 12 feet forms the limit to which a parapet can conveniently be thrown up, further height necessary for protection is obtained by sinking the ground to be defiladed before the parapet's base. In measuring for these heights, the instruments used are *boning-rod*s, which are fixed in the ground at D and B, with the normal height of a man marked on them; a third rod at A is then marked at the point where the line of sight between the normal points on the two others intersects it, and so shows the height of the parapet.

The foregoing parapet has been provided only as a straight breastwork, deriving its safety solely from its own fire in a direct line upon the besiegers; but in practice such a rampart would be

Fig. 5.

exposed to the disadvantage of holding but little command over the *scarp* or *escarp* (part cut away) at its foot; so that, if approached under cover, an enemy could readily lodge himself therein. To guard against this a work is *flanked*, so that the fire of one part shall take in flank an enemy advancing against another part. See fig. 5, where ABCDE is a flanked or reciprocally defensive parapet, in which it is evident that the fire from AB, DE, must take in flank any force moving on BC or CD, while the latter also, in like manner, flank AB, DE, themselves. In a flanked defence of this sort, the angles, A, C, E, which project towards the country, are technically termed *salient angles*; those at B and D, *re-entering angles*. The flanked parapet has often, likewise, the power of defilading larger spaces than the simple line of parapet, since the salient angles can, perhaps, be brought on elevated ground; while the re-entering angles, though with less elevation, may in some degree compensate that defect by greater distance from the front. A disadvantage of flanked defences is, that the hostile fire crosses the parapet at a less angle than in the straight line, and may, therefore, be more deadly; indeed, the object of the assailant will always be to obtain an enfilade fire along one or

more parapets of the defence, as (in fig. 5) an enemy posted at F, would be able to sweep the complete line of the parapet CB. To avoid this, the engineer who constructs the works must ascertain minutely the elevation of the surrounding points, and make his salients at such angles that the prolongation of his parapets towards the enemy shall always fall on low ground, whence no command can be obtained.

Now, where the salient angle becomes somewhat acute, and there is an enemy on both fronts, the soldiers defending the right parapet, and standing on its banquette, would be exposed to a *reverse* or back fire from the enemy in front of the left parapet, beyond the defilading of which they would doubtless be. As a remedy, an internal parapet, called a *traverse*, or, from its duty, a *parados*, is raised between the parapets of the salient, its height being determined on precisely the same principles as were made use of in regard to the original parapets.

Where both the faces of the salient are unavoidably so placed as to be enfiladed, a small work, called a *bonnet*, is constructed at the angle, which consists in the parapet being so raised up to an extra height of twelve feet if necessary, and at the same time widened, that the banquette shall be defiladed. If a height of twelve feet is insufficient to defilade the whole length of the banquette, traversing parapets must be raised at right angles to the face of the work, and within it, at such distances that the whole

may be safe: of course, the height of the bonnet and of the traverses must be decided on rules analogous to those explained in fig. 4. The increased height of the parapet of the bonnet renders it necessary to have two or more banquettes at that portion of the work, with steps to aid the ascent (see section in fig. 6); as AB, the crest

Fig. 6.—Bonnet.

of the general parapet, with banquette at C; and DE, the bonnet, with banquettes at F and G.

In enclosed work—i. e., in works entirely surrounded by parapets—the position of the *parados* is of vital importance; and they have often to be devised with great ingenuity, so as to protect the defenders from reverse fire in any direction, and at the same time not to prevent necessary communication between different portions of the fortress.

Relief means the height of any point in a work above the plane of construction, which may be the line of sight or the bottom of the ditch. In the latter case, the relief of the parapet is an important item in estimating the resisting power of a work, as it represents the vertical equivalent of the obstacle which will be offered to a foe.

When the relief of the parapet's crest has been determined, its thickness becomes the next consideration. The dimensions are laid down on the ground, and depend, first, on the angle at which the material to be used will pile; and then, on the nature of the missiles against which the parapet is to afford protection. For example, an earthwork of from three to four feet suffices to resist musketry; a thickness of 18 feet is impervious to the 24-pounder; while large guns can pound through even more solid obstructions.

Taking fig. 7 as an example, in which *a* is the crest of the parapet, then the banquette *e* should, for convenient firing, be four feet three inches below *a*; its width three feet, if for a single line of soldiers; four feet six inches for a double rank; its slope

Fig. 7.—Section of Parapet, Ditch, and Glacis.

should be one in twelve, that water may run freely off. The base, *de*, of the slope, up which the men mount to the banquette, should be twice its height *de*, and cut into steps with inclined sides, to allow of easy ascent; and where the height is considerable, a supplemental banquette (on which relieving-men can, if necessary, reload), is desirable. The interior slope, *ac*, of the parapet should be one in four; the exterior slope, or *plongée*, *ad*, intended for the direction of the guns on an assailant, one in six, a deviation being permitted between one in nine and one in four: but the crest being more liable to destruction as the slope of *ad* is augmented, it is best to keep it as small as circumstances will allow; one in six is the ordinary slope in English fortification, the angle of the interior slope being constant. In some continental services, however, the angle, *ead*, is kept constant at 100°, by increasing the deviation of the interior slope of the parapet from the perpen-

dicular as the plunge of the exterior is greater. The flatter, however, the crest of the parapet is the better, as sand-bags are in certain cases ranged on it to form cover for the men, while they fire through loopholes left in this additional defence. Earth of medium tenacity maintains its position properly when sloped at an angle of 45°; and this is the greatest angle which can be counted on for the outer slope of the parapet. The scarp, *l*, and counterscarp, *m*, of the ditch need not have so great an incline, as the ground in which they are cut has usually had time, and the footsteps of ages, to consolidate it. In such cases, the base of the triangle is frequently made equal to half the perpendicular. Cases, of course, occur in which steeper banks are considered indispensable; and then, to prevent slips, the earth must have a coating to keep it up, which may be of fascines, hurdles, planks, or sand-bags, for temporary works, or those constructed in the midst of action; while the most solid masonry performs the same function in fortresses of a more permanent nature. This outer coating is denominated a *revêtement*.

In fig. 7, *ghi*, is the *glacis*, formed during the excavation of the ditch, and having for object the bringing of an advancing enemy into the best line of fire from the parapet. The base and perpendicular of its interior slope, *gh*, should be equal; the slope of the outer face should be one in twelve, unless the slope of the ground render some different angle desirable. An advanced glacis, *k* in fig. 7, is sometimes adopted, in order that the enemy may the sooner be brought under fire. It is absolutely necessary that the crest of the parapet should be five and a half feet higher than the crest of the glacis, as, otherwise, an assailant having reached the latter, would be able to pour a musketry-fire over the former into the work.

No part of any glacis, whether near or advanced, should be more than two feet below the line of fire from the parapet—i. e., the line joining the crests of the parapet and glacis continued; if more depth be allowed, the enemy may advance in a crouching posture, without being liable to be hit. Advanced glacis are usually made of earth thrown up in prolonging beneath the ground the plane of the preceding glacis. They may be defended entirely from the parapet, in which case palisades or abatis are often fixed (as in fig. 7) to delay the advancing enemy when at the point of greatest exposure. On the other hand, these advanced glacis are occasionally defended as a series of advanced intrenchments, and only abandoned, one by one, as the defenders are driven in towards their main work.

The dimensions of the ditch depend in some measure on the amount of earth required for the parapet and glacis; but in addition to being the mine whence the materials for the latter works are drawn, the ditch must also oppose a considerable obstacle to any hostile advance. To do this effectually, the minimum width across the top is 18 feet; its depth need only be limited by the trouble of raising the earth; but in practice 12 feet is found the greatest which can be conveniently arrived at. Having ascertained the profile of the parapet, with its banquette or banquettes, bonnets, traverses, glacis, &c., it becomes a mere matter of mensuration to complete the area of a section, to multiply it by the length, and so to obtain the cubic feet of earth required. With the length of the ditch known, a very simple calculation then exhibits its width and depth—a small allowance being made for the fact that the earth dug out from the ditch, where it has probably been long compressed, will occupy somewhat more space when thrown up, and broken into clods, for forming the parapet.

The *scarp*, or inner face of the ditch, is most difficult of ascent

by the assailant, when in a continuous line with the parapet (as in fig. 7); but sometimes it would be dangerous to construct the work with this continuity, as damage to the scarp would jeopardize the stability of the parapet. In these cases a narrow step, called a *Berm* (q. v.) of from two to four feet, is made to intervene between the foot of the parapet and top of the scarp: as a precaution, it is covered with all possible obstacles to any lodgment being effected on it by the enemy. When a berm is employed, greater steepness is usually given to the scarp.

The *counterscarp*, or outer sloping side of the ditch, should be somewhat steeper than the scarp. The bottom of the ditch should slope from both sides towards the center, to carry off the water; and obstacles should be scattered about to prevent an enemy from forming his troops in the ditch.

EARTHWORKS IN FIELD FORTIFICATION.—As the most readily

constructed, earthworks naturally recommend themselves to the engineer, who, in the field, is called upon to defend the position of an army against sudden attack. Their utility has been shown in their employment from the earliest times; and modern experience tends to prove that earth-parapets are of all fortifications among the most difficult to overcome. An army manœuvring before a superior force, can scarcely hope to avoid battle being thrust upon it, unless, strengthened by fieldworks, it be rendered more nearly equal to the adversary. Napoleon, Marlborough, Eugène, Wellington, have given their names as witnesses to the indispensability of such works. The Russian parapets at Borodino made the French victory so sanguinary a triumph that it was useless to the victors. A few redoubts at Pultowa saved Peter the Great from total defeat by his formidable Swedish rival. The world-famed lines of Torres Vedras enabled Wellington with 50,000 troops, half of whom were untried Portuguese, to withstand for five months, and ultimately to drive back, the hitherto victorious army of 70,000 French, under such commanders as Masséna, Ney, and Junot. The earthworks surrounding Sevastopol partook greatly of the nature of fieldworks for the protection of a large army, and history will not forget to recount the resistance they offered for almost a year to the best troops of the civilized world.

For a line, whether of earth or masonry, to be efficient, it must combine artillery fire with that of musketry. The guns will generally be so placed as to command some specific line of approach, such as a ravine, a line of abattis, or some portion of the glacis. They should themselves be as little exposed as possible, nor should the gunners be uncovered more than is absolutely requisite. To effect this, the gun is generally made to fire through an *embrasure* (q. v.) in the parapet, instead of over the latter. The embrasure is a cutting through the solid parapet, 20 inches wide at its inner extremity, and outwards half as much as the width of the parapet. In cases where it is necessary, for proper command, that the line of fire should not be lower than the top of the parapet, the embrasure is made through an additional parapet—raised, as in the previous case of the bonnet, above the original one. The bottom of the embrasure is called the *sole*, and slopes downward sufficiently to allow of a certain depression being given to the gun. The remainder of a parapet below the sole is the *genouillère* (from *genou*, a knee), and in field fortification should be three and a half feet high; the portion between two embrasures is the *merlin* (Ital. *merlone*, battlement); and an embrasure need not cut the parapet perpendicularly, an angle being admissible, when an oblique fire is necessary. When, however, the obliquity would exceed 70° , it is usual, in order that the thickness of the parapet should not be too much diminished, to form a projecting angle in it, through which the embrasure is cut (as in fig. 8). The sides of the embrasures are *cheeks*, and require revêting.

A *barbette* is a platform raised behind a parapet, higher than the general interior, with a view to guns being fired from it over the parapet.

There are certain fixed rules in all fortification, such as:—1. The length of lines must never exceed musketry range, or the flanking-works would become ineffective for their object. 2. The angles of defence should be about right angles. 3. Salient angles should be as obtuse as possible. 4. Ditches should have the best possible flanking. 5. The relief of the flanking-works must be determined by the length of the lines of defence. 6. The value of almost every detached work depends on the support it can give to or receive from an army or other work or works. 7. The reduction of every fortified work is merely a question of time; and a work fairly surrounded is sure to fall, unless relieved from without.

Fieldworks, which, it must be borne in mind, are intended mere-

Fig. 8.

Fig. 9.

Fig. 10.—Bastioned Fort.

stand the nature of a single bastion, see A (fig. 10), which represents one at the corner of a square work; *ab* is the left flank; *bc* the left face; *cd* the right face; *de* the right flank; *ae* is the gorge; *af*, *fe* are the *demi-gorges*, being continuations of the sides, or curtains, of the work; *a* and *e* are the left and right curtain angles; *b* and *d*, the left and right shoulder angles, and *c* is the flanked angle.

Continued lines are simple parapets, either connecting fortified posts, or covering the front or flank of an army. Redans joined by curtains (as in fig. 11) are those most easily constructed; but as the ditches can only be defended by an oblique fire, the curtains are occasionally so broken

Fig. 11.—Continued line of Redans.

as to form nearly right angles with the faces of the redan, as in the dotted line; they then become *lines of tenailles*.

Lines en Crémallière have long faces with perpendicular flanks. *Lines with intervals* are often as effective as continued lines. They consist of detached works in two lines, within musketry fire of each other. The re-entering angle, *abc* (fig. 12), should as nearly as practicable be a right angle. The celebrated lines of Torres Vedras, before adverted to, consisted of 150 detached forts.

Tête-du-pont, is a work constructed to cover the approaches to a bridge, and will be found described under BRIDGE-HEAD.

A *tenaille* is the reverse of a redan, and consists of two faces forming a re-entering angle: it can only be used in connection with some other work.

A *flèche* is a breastwork of two faces, forming a salient angle, constructed on the exterior of a glacis, usually at its foot, in order to defend the ground before a bastion or ravelin.

Having now explained the principal forms which elemental works of fortification are made to assume, we proceed to describe—very briefly, of course—the systems into which these have been

Fig. 12.—Line with intervals

incorporated for the defence of fortresses, towns, and other permanent purposes. It will merely be necessary to state, in addition to what has been already written, that a *rampart* is a raised structure of earth or stone, above the mean level of the country, on which the parapets, &c., can be thrown up, and which affords to the town or space protected the extra cover of its height, while it elevates the inner works sufficiently to enable them to command and fire over those situated exteriorly to themselves. It need scarcely be said that a line which can be made of earth may equally be constructed of any other material which circumstances may render desirable, the maximum resistance and minimum liability to splinter being the qualities to be chiefly considered.

SYSTEMATIC FORTIFICATION FOR PERMANENT WORKS.—Adverting to the most ancient fortifications mentioned in history, we find Greek cities surrounded with walls of brick and rubble, and occasionally of stone in huge blocks. Babylon had a wall of prodigious circuit—100 feet high, 32 feet thick, and surmounted by towers. Jerusalem, at the time of Vespasian's siege, had similar walls with masonry of enormous solidity. These seem to represent fortification as it stood from the time of that emperor to the introduction of cannon for breaching purposes. Then the square and round towers, which had formed sufficient flanking defence against arrows, proved useless when cannon-balls, fired from a distance, were the instruments of assault. At the same time, the walls, which had resisted battering-rams, crumbled to atoms under the strokes of artillery.

Fortunately, however, the art of defence has always made equal progress with that of attack; and, early in the 15th, if not late in the 14th c., the Italians had commenced to flank their walls with small bastions. The bastions at Verona, built by Micheli in 1523, are usually looked upon as the oldest extant specimen of modern fortification. Tartaglia and Albert Dürer, painter and engineer, were early in the field. In most of the earlier systems the face of the bastion was perpendicular to its flank. The first principles were successively improved by Marchi, an Italian, who died 1599, by Errard Bois-le-Duc, and the Ville, under Henry IV. and Louis XIII. of France. The Count de Pagan, whose treatise appeared in 1645, did much towards demolishing previous errors, and laid the basement of that science which Vauban subsequently wrought almost to perfection. Born in 1633, Vauban had a genius which penetrated in every direction, equally in the ways of war and in those of peace. He might possibly have taught how fortresses could be rendered impregnable, had not the restless ambition of his master, Louis XIV., led him to demonstrate, first, that the reduction of any work was a mere question of time and powder. His talent so improved the system of attack, that even he himself could not construct a rampart that should withstand the fire conjured up against it by his discoveries. He constructed 33 new

fortresses, improved above 100, and conducted personally more than 50 sieges. To him are soldiers indebted for the sweeping fire of ricochet, and to him in a degree for the traverses which endeavor to render it harmless. Coehoorn, director-general of the

fortresses of the United Provinces, was the contemporary, rival, and opponent of Vauban; his master-piece is Bergen-op-Zoom. Cor-
montaigne, Belidor, Montalembert, Boussard, and Carnot may also be mentioned as conspicuous masters in the science.

Irrespective of irregularities in the form of the place to be defended, a particular polygon is selected as that on which the lines of defence are to be drawn. Each side of this is a *face of defence*, and the length of a side is rarely made greater than 360 yards.

Vauban's first system is shown in fig. 13 as regards the outline of its ground-plan; fig. 14 displaying the same in profile.

In this instance, the polygon taken is an octagon. Let *ab* (fig. 13) be a side of this polygon; bisect this in *c*, and draw a perpendicular to *ab*. On this, inwards, mark off *cc'* one-sixth of *ab*; join *ac*, *bc*, and produce the lines; then from *a* and *b* respectively mark off *ad*, *bg*, each equal to $\frac{1}{2}$ *ab*, for the faces of the bastions. Next, from *a* and *b* as centers, with radius, *ag*, describe arcs cutting *ac*, *bc*, produced in *f* and *e*; join *de*, *fg*, for the flanks of bastions, and *ef* for the curtain of the work. The first line of defence is then complete, the necessary parapets, &c., being of course raised on the site laid out. From an examination of this, it will be seen that the whole space in the front is covered. The faces of the bastions and the curtain command more or less the entire front, while the bastion flanks sweep along the faces of adjoining bastions and along the curtain. In front, however, of the apex of each bastion, the line of advance is only covered by an extremely oblique fire. To obviate this, a ravelin, *F*, is constructed on the further side of the main ditch, which commands the double fronts, and, at the same time, forms an outwork capable of assisting in the general scheme of defence. To trace the main ditch, describe from the flanked angle of the bastion, *a* or *b*, an arc with radius 30 yards (if dry ditch, 36 if wet), and from these arcs draw tangents to the shoulders, *d* and *g*, of the opposite bastions. These tangents, meeting in the line *cc'*, form the counterscarp line of the main ditch. From *h*, the re-entering angle of the counterscarp, set off 100 yards along the perpendicular to *i*, which will be the apex of the flanked angle of the ravelin. From *i*, draw lines to points situated in the faces of the bastions, 10 yards from the shoulder angles; these lines to the points intersecting the counterscarp give the faces of the ravelin. The ditch of the ravelin is 20 yards wide, with counterscarp parallel to the escarp. The zigzag line now arrived at gives the inner side of the covert-way—10 yards wide—behind the glacis, which last slopes gradually towards the country, and is ordinarily the outer work of all. The tenaille is a comparatively low parapet sweeping the depressed interior of the ravelin, and commanded by the bastions and curtain.

The caponnière, forming a communication between the tenaille and the ravelin, consists of a passage between two low parapets, each with a glacis sloping towards the ditch, which is swept from the work.

Nine feet clear are allowed round the traverses on the covert-way; at the re-entering angles of the covert-way, *places of arms* are formed by setting off 30 yards on each side, and with this as gorge, advancing faces inclined to each other at 100°. If the polygon had been a square, *cc'* would have been $\frac{1}{2}$ *ab*; if a pentagon, $\frac{1}{3}$ *ab*; and for any polygon of more sides than seven, $\frac{1}{4}$ *ab*.

Vauban's second and third systems were those in which he adapted old walls to his modern improvements. Availing himself of the works already formed, he added counterscarps in front of the corner-towers, thereby making hollow bastions, and avoiding the necessity of entirely rebuilding.

Coeboorn's system had counterscarps in front of the bastions and parallel to them. The flanked angle of his ravelin had a fixed value—viz., 70°.

Cormontaigne widened the gorge of his ravelin, thereby reducing the length of the bastion face available for breaching from without. He also revived the step-like formation of the covered way, originally seen in Speckle in the 16th c., and which gives defenders a continued line of fire from each traverse along the covert-way.

The modern system differs but little from that of Cormontaigne. The re-entering places of arms have circular fronts instead of angular; the angle of the ravelin is fixed at 60°, and all the best points of older styles are associated.

Fig. 15 is intended to present at one view a representation of the systems in force since artillery came into common use, as well as the gradual transition from square towers on castle walls to flanked bastions on modern lines. The elements of fortifying against shipping will be found under MARINE FORTIFICATION; the principles of attacking fortresses generally, under SIEGE, and MINES, MILITARY.

FORTIGUE'RRRA, NICOLÒ, an Italian poet, was born at Pistoja, November 7, 1674. Destined from youth for the church, he proceeded to Rome at an early period, where the power of the prelate Carlo A. Fabroni, who was his relative, speedily secured him advancement, and where he was ultimately raised to the dignity of prelate and papal chamberlain by Clement XI. An ardent cultivator and protector of letters, it must be owned that F.'s own compositions are more prized for a certain rich joviality of imagery, and profuse facility of language, than for any salient beauty of style or conception. His chief work, *Il Ricciardetto*, was

originally commenced in confutation of friends, who maintained that the striking ease and fluency of Ariosto, Berni, and other poets of a similar school, were but apparent, and in reality the fruit of deep art and severe labor. F., in a few hours threw off an entire canto of *Il Ricciardetto*, strikingly in imitation of the above poets, and continued the work at random much beyond its originally designed limits. It was published in 1738, two years after his death, and met with unequivocal favor, notwithstanding the incredible incidents and licentious images with which it is replete. F. died 7th February 1735.

FORTRO'SE, or FORTROSS, a parliamentary and royal burgh, seaport, and watering-place in the east of Ross-shire, on the west side of the Moray Firth, opposite Fort George, ten miles north-north-east of Inverness. Pop. (1881) 874. It unites with Inverness, Forbes, and Nairn in sending a member to parliament. F. had a fine cathedral and a bishop's palace; but both of these buildings were partially destroyed under Cromwell, and the stones sent to Inverness, to be used in building a fort there. F. is now of little importance, but, in the 16th c., it had a considerable trade, and is said to have been the seat of arts, science, and divinity in the north of Scotland. Previous to 1444 it was known by the name of Chanonry, but in that year it was united with the adjacent burgh of Rosmarkie under the name of Fortross.

FO'RTS and FORTALICES. The military power of the state is intrusted by the constitution of this country to the sovereign. After having been unconstitutionally claimed by the Long Parliament in the time of Charles I., it was again vindicated for the crown by 2 Car. II. c. 6. This branch of the royal prerogative extends not only to the raising of armies and the construction of fleets, but to the building of forts and other places of strength. Sir Edward Coke lays it down (1 Inst. 5), that no subject can build a house of strength embattled without the license of the king; and it was enacted by 11 Henry VII. c. 18, that no such place of strength could be conveyed without a special grant.

FORTU'NA, called by the Greeks *Tyche*, was in classical mythology the Goddess of Chance. According to Hesiod, she was a daughter of Oceanus; according to Pindar, a sister of the Paræe. She differed from Destiny or Fate, in so far that she worked without law, giving or taking away at her own good pleasure, and dispensing joy or sorrow indifferently. She had temples at Smyrna, Corinth, and Elis. In Italy, she was extensively worshipped from a very early period; and had many names, such as *Patricia*, *Plebeia*, *Equestris*, *Virilis*, *Primigenia*, *Publica*, *Privata*, *Muliebris*, *Virginensis*, &c., indicating the extent and also the minuteness of her superintendence. Particular honors were paid to her at Antium and Præneste; in the temple of the former city, two statues of her were even consulted as oracles. Greek poets and sculptors generally represented her with a rudder, as a symbol of her guiding power, or with a ball, or wheel, or wings, as a symbol of her mutability. The Romans proudly affirmed that when she entered their city, she threw away her globe, and put off her wings and shoes, to indicate that she meant to dwell with them for ever.

FORTUNATE ISLANDS. See CANARIES.

FORTUNA'TUS is the title of one of the best people's books (*Volksbücher*) ever written. It originated about the middle of the 15th c., though many of the tales and legends included in it are of much older date. The opinion that it was worked up into German from a Spanish or English original may be considered as set aside. The substance of the book is that F., and his son after him, are the possessors of an inexhaustible purse of gold and a wishing-cap, which, however, in the end, prove the cause of their ruin. The moral is, that worldly prosperity alone is insufficient to produce lasting happiness.

The oldest printed edition of the book now extant bears the date Frankfurt am Maine, 1509. Later German editions mostly bear the title, *Fortunatus, von Seinem Seckel und Wunsch-hütlein* (Fortunatus: Story of his Purse and Wishing-cap. Augsb. 1530; Nürnberg, 1577; and Basel, 1699). It has been reprinted in Simrock's *Deutsche Volksbücher* (3 vols., Frankt. am Maine, 1846). Various French versions of the German story have appeared from time to time, as the *Histoire de Fortunatus* (Rouen, 1670); which served as the groundwork of the Italian *Avvenimenti de Fortunatus e de' Suoi Figli* (Naples, 1676). From the German original, have also sprung, among others, the Dutch version *Een Nieuwe Historie van Fortunatus Borse en van Zijnen Wensch hoed* (Amst. 1796); later, the English *History of Fortunatus and his Two Sons* (London, no date); the Danish *Fortunati pung og ønskehat* (Köpen. 1664, 1672, 1695, 1756, 1783); the Swedish *Fortunatus* (1694); and about 1690, two Icelandic versions, one in verse and another in prose. The first to dramatize the subject was Hans Sachs, in his *Der Fortunatus mit dem Wunschseckel* (1553), after whom comes the English Thomas Decker with his *Pleasant Comedie of Old Fortunatus* (1600), a work which had the honor to make its reappearance in German about the year 1620. The most poetical edition of the story is that given by Tieck in his *Phantasus* (3 vols., Berlin,

1816). See Grässe's *Die Sagenkreise des Mittelalters* (Dresd. and Leip. 1842), and Ersch and Gruber's *Encyclopædie* (sect. 1, vol. 46).

FORTUNE, ROBERT, a distinguished botanist and traveler, was born in the county of Berwick in 1813. After completing his education at a Scotch parish school, he served an apprenticeship as a gardener, and obtained employment in the Royal Botanic Garden at Edinburgh. There he had good opportunities of obtaining a sound knowledge of botany and the higher departments of his own profession, so far as they relate to the cultivation of subtropical and tropical plants under glass in a temperate climate, and these opportunities he turned to good account. He afterwards obtained a situation in the garden at Chiswick, where his abilities and acquirements attracted the attention of London naturalists. He was, in 1842, sent by the Botanical Society of London to Northern China to make a botanical exploration of the country. His journey was most successful, and he sent home a very large number of new and valuable plants. He gave an account of his adventures in his *Three Years' Wanderings in Northern China*, a work which places its author in the foremost rank of contemporary explorers. F., on his return to England, acted for a time as curator of the Physic Garden at Chelsea. In 1842, he was appointed by the East India Company to proceed to China to make investigations relative to the cultivation of the tea-plant; and on his return to England he published a work entitled *Two Visits to the Tea Countries of China*. He was afterwards employed by the American government to collect for them seeds, chiefly those of the tea-plant, in the East. It was F. who introduced the tea-plant from China into the North-west Provinces of India. *Yedo and Peking*, published in 1863, devotes special attention to the natural productions and agriculture of the districts visited. F. died at London, 13th April 1880.

FORTUNE-TELLER. Under the designation Vagabonds, in the Scottish Act 1579 c. 74, are included all who go about pretending to foretell fortunes. The punishment inflicted on them by the statute is scourging and burning on the ear.

FORT WAYNE, a flourishing town of the state of Indiana, North America, at the confluence of the St. Joseph and St. Mary rivers, which form the Maumee, and on the Wabash and Erie Canal, 122 miles east-north-east from Lafayette. It is a great railway center, and its growth has been very rapid. A fort was erected here by order of General Wayne in 1794, and it continued to be a military post till 1819. Pop. (1870) 17,718; (1880) 26,881.

FO'RUM, a Latin word, which originally signified an 'open place,' and is probably connected with *foras*, 'out-of-doors.' The Roman *fora* were places where the markets and courts of justice were held. The former were termed *fora venalia*, and the latter *fora judicialia*. Of the *fora judicialia*, the most ancient and celebrated was the *forum Romanorum*, or *par excellence*, the *forum magnum*, occupying the quarter now known as the *campo vaccino* (or cattle-market). It stretched from the foot of the Capitoline Hill, where the arch of Septimius Severus stands, to the temple of the Dioscuri, was seven *jugera* in extent, and was surrounded by streets and houses. The boundary on the east and north was the *Sacra via*, of which the side nearest to the forum was left open; while on the other were corridors and halls, such as those of the *argentarii* (bankers or money-changers). At a later period, the site of these was, for the most part, occupied by basilicas and temples. In the eastern portion of this space, were held the earliest *Comitia* (q. v.) of the Romans—the *comitia curiata*; hence this part took the name of the *comitium*, and was distinguished from the forum strictly so called. Here were hung up for the benefit of the public the laws of the Twelve Tables; and, after 304 B.C. the *Fasti* written on white tables to inform the citizens when the law-courts were open. The *Forum*, in the narrower usage of the word, probably ceased to be employed as a market-place about 473 B.C., when it became the place of assembly of the *Comitia Tributa*. Of the later *fora venalia*, the principal were the *forum boarium* (the cattle-market), the *forum suarium* (pig-market), *piscatorium* (fish-market), *olitorium* (vegetable market), &c. Public banquets for the populace, and the combats of the gladiators, were in the time of the republic, usually held in the great forum, which also contained monuments of various kinds, of which may be mentioned the famous *Columna Rostrata* of C. Duilius, erected in memory of his victory over the Carthaginians. The rostra, or platforms from which public orations were delivered, formed the boundary between the forum in its narrower usage and the *comitium*. After the time of Julius Cæsar and Augustus, the *Forum Romanorum* lost the importance it had previously derived from being the central point of Roman political life. The other two *fora judicialia* were the *Forum Julii* and the *Forum Augusti*. Compare Becker, *Handbuch der Röm. Alterthümer* (1 vol., Leipsic, 1843).

FORUM CO'MPETENS, in Law, is the court to the jurisdiction of which the party is amenable.

FOSCARI, FRANCESCO, Doge of Venice from 1423 to 1457, a brilliant period of conquest and prosperity to his country, and of unexampled affliction to himself and family. Born about 1370, his aspiring ambition soon fired him with passionate eagerness to exalt his reign by the glory of conquest, and speedily involved the state in a severe conflict with the Dukes of Milan; which, however, the doge's great military ability in the end turned into a source of glory and aggrandizement to Venice. His triumph was embittered by the successive loss of three sons; and the one who remained to transmit the name, and succeed to the inheritance of the family, was, in 1445, denounced for having received bribes from the hostile generals, to use his influence with the doge in procuring less rigorous terms. Tried for this grave crime before the Tribunal of the Ten, and racked cruelly in view of his father, Giacompo Foscari was banished for life, under pain of death should he attempt to revisit his native land. In 1450, the assassination of one of the 'Council of Ten,' Hermolao Donati, was imputed, on what seem most unfounded grounds, to Giacompo, who was consequently summoned from his exile, tried, tortured, and banished a second time on still more rigorous terms to the island of Candia. Grown reckless through suffering, and longing to see his home and country on any terms, Giacompo petitioned the Duke of Milan to intercede in his behalf with the senate, a step which, by Venetian law, was punished as a high crime, and led to the unfortunate Giacompo being for the third time subjected to torture and renewed banishment, on entering into which he died of grief. The doge had vainly besought to resign a dignity grown loathsome to him, from its imposing the barbarous obligation of witnessing his son's torture; but in the end he was deposed, and ordered to vacate the palace in three days. At the age of 87, decrepit from years, and bowed by sorrow and humiliation, Francesco F., supported by his venerable brother, descended the Giant's Staircase, and passed out for ever from the ducal palace, the scene of such vain pomp and bitter misery. Pasqual Malapieri was elected in his stead in 1457, and at the first peal of the bells in honor of elevation, F. expired from the rupture of a blood-vessel. Byron has written a tragedy on the subject, entitled *The Two Foscari*.

FO'SCOLO, Ugo, an Italian author, was born about 1778, at Zante, one of the Ionian Isles, and proceeded to Venice in his 16th year, where for a time he pursued his studies, repairing later to Padua to enjoy Melchiorre Cesarotti's noble course of classic literature. His earliest efforts at poetical composition were strictly modelled on his favorite Greek classics; and, as early as 1797, his tragedy, *Il Tieste*, was received with favor by a critical Venetian audience. The dismemberment of the Venetian states decreed by the treaty of Campo Formio, bitterly incensed F.'s patriotic spirit, and inspired him with one of his most remarkable works, *Le Lettere di Jacopo Ortis*, which, owing to the fierce political excitement then prevailing throughout the entire peninsula, was received with immense popularity. F. repaired to Milan on its being declared the capital of the Cisalpine republic, and there obtained the grade of officer in the Lombard legion.

On the downfall of the republic, he retreated with the French into Genoa, where, in the midst of the terrors of a rigorous siege, he composed two exquisite odes to *Luigia Pallavicini Caduta da Cavallo*, and *All' Amica risanata*. F. subsequently entered France with the intention of joining Napoleon's expedition against England, and prepared a much admired version of Sterne's *Sentimental Journey*, to exercise himself in English. On the failure of the plan, he returned to Milan, and prepared a splendid edition of Montecuculi's works, with notes and historical references—*Opere di Raimondo Montecuculi, per Luigi Mussi* (Milan, 1807–1808), a very rare edition. At this time, he also published his exquisite poem, in blank verse, *I Sepolcri*, which at once placed him among the classic authors of his country. In the same year, he was appointed to the chair of eloquence in Pavia, and occupied the post, until the professorship was suppressed in all the colleges of Italy. His inaugural address, *Dell' Origine e dell' Ufficio della Letteratura*, is a masterpiece of beautiful, noble, and patriotic writing. *Ajace* and *Ricciarda* are tragedies. From the time F. lost faith in the sincerity of Bonaparte's intentions to his country, he employed the full powers of his wrath and sarcasm in denouncing his treachery. After various vicissitudes, F. finally sought refuge in Britain about 1816, and soon mastered the language sufficiently to contribute to the *Quarterly* and *Edinburgh Reviews*. In London, some of his best writings were published—viz., *Essays on Petrarca and Dante*, *Discorso sul testo del Decamerone*, *Discorso storico sul testo di Dante*, and various minor compositions. He died October 10, 1827, of dropsy, near London. His remains were finally deposited in the church of Santa Croce, Florence, in 1871. His works and letters were published in 12 vols. by Le Monnier (1850–1862).

FOSS, or FOSSE (Lat. *fossa*, from *fodio*, I dig), in Fortification, is a ditch or moat, either with or without water, the excavation of which has contributed material for the walls of the fort it

is designed to protect. The foss is immediately without the wall, and offers a serious obstacle to escalading the defences.

FOSSA ET FU'RCA, or PIT AND GALLOWES, was an ancient privilege granted by the crown to barons and others, which implied the right of drowning female felons in a ditch, and hanging male felons on a gallows.

FOSSA'NO, a town of Piedmont, N. Italy, in the province of Coni or Cuneo, is situated on the left bank of the Stura, on a hill surmounted by an old castle, 14 miles north-east of Coni. It is surrounded with old walls, and is well built; but the houses are erected over arcades, under which run the footways, and thus the streets have a somewhat gloomy appearance. It has a handsome cathedral, ten churches, a royal college, and numerous minor educational institutions, silk-factories, paper-mills, and tanneries. Pop. (1871) 7272.

FOSSIL (Lat. *fossilis*, dug out of the earth), a term formerly applied, in accordance with its derivation, to whatever was dug out of the earth, whether mineral or organic, but now restricted to the petrified remains of plants and animals imbedded in the earth's crust. They were formerly, and are sometimes still, called petrifications. They occur in nearly all the stratified rocks, which have, on this account been called Fossiliferous strata. It is difficult or impossible to detect them in the metaphoric rocks, for the changes that altered the matrix have also affected the organisms, so as either almost or altogether to obliterate them. In the fundamental mica-schist and gneiss they have escaped notice, if ever they existed; but comparatively recent investigation has proved their presence in or among those gneissose rocks which are the greatly metamorphosed representatives of the Lower Silurian Measures in the north of Scotland. See GNEISS.

The conditions in which fossils occur are very various. In some Pleistocene beds the organic remains are but slightly altered, and are spoken of as sub-fossil. In this state are the shells in some raised sea-beaches, and the remains of the huge struthious birds of New Zealand, which still retain a large portion of the animal basis. In the progress of fossilization, every trace of animal substance disappears; and if we find the body at this stage, without being affected by any other change, it is fragile and friable, like some of the shells in the London clay. Most frequently, however, a petrifying infiltration occupies the cavities left in the fossil by the disappearance of the animal matter, and it then becomes hardened and solidified. Sometimes the whole organism is dissolved and carried off by water percolating the rock, and its former presence is indicated by the mould of its outer surface, and the cast of its inner in the rocky matrix, leaving a cavity between the cast and the mould agreeing with the size of the fossil. This cavity is occasionally filled up with calcareous spar, flint, or some other mineral; and we thus obtain the form of the organism, with the markings of the outer and inner surfaces, but not exhibiting the internal structure. The most advanced and perfect condition of fossilization is that in which not only the external form, but also the most minute and complicated internal organization is retained; in which the organism loses the whole of its constituents, particle by particle, and as each little molecule is removed, its place is taken by a little molecule of another substance, as silica or iron pyrites. In this way we find calcareous corals perfectly preserved in flint, and trees exhibiting in their silicified or calcified stems all the details of their microscopic structure—the cells, spiral vessels, or disc-bearing tissue, as well as the medullary rays and rings of growth.

FOSSIL FERNS. As far as has been yet determined from the rocky tablets of the earth's crust, ferns first appeared in the Devonian period, but then only sparingly, not more than nine or ten species having been observed. In the immediately succeeding Coal-measures, they suddenly reached their maximum development. The dense forests and the moist atmosphere of this period were so suited to their growth that they formed a large bulk of the vegetation. Upwards of 350 species have been described, some of them tree ferns of a size fitting them to be companions of the immense Sigillarias and Lepidodendrons whose remains are found associated with theirs in the Carboniferous rocks. Twenty-three species have been found in Permian strata. Many new forms appear in the Trias, and their number is increased in the Oolite. The fresh-water beds of this period contain numerous beautiful ferns, upwards of fifty species having been described. The marine beds of the Cretaceous period contain very few forms, and in the Tertiary rocks they are equally rare.

FOSSILIFEROUS ROCKS are those which contain organic remains. If we except the lowest metamorphic rocks, in which, as yet, no fossils have been found, the term is equivalent to the 'stratified rocks,' when used comprehensively; but it may also be applied to a particular bed, as when we speak of an unfossiliferous sandstone compared with the neighboring fossiliferous shale or limestone.

FOSSOMBRO'NÉ, a small episcopal town of Italy, in the province of Urbino and Pesaro, is pleasantly situated on a hill on the left bank of the Metauro—which is here spanned by a fine modern bridge—11 miles east of the town of Urbino. It rose in the 14th c., from the ruins of *Forum Sempronii*, destroyed by the Goths and Lombards. Some interesting Roman inscriptions and remains of the ancient city are contained in the cathedral of St. Aldobrando. F. is celebrated for its fine manufactures of carpets and woollen cloths, and particularly for the excellent silk of its neighborhood. Three miles from F. is Il Monte d'Asdrubale, famous as the scene of the engagement in which the Carthaginian general was defeated and killed by the Romans in 207 B.C. Pop. about 4500.—See Lauro Giacomo, *Historia e Pianta di Fossombrone*.

FOSTER, JOHN, a well-known English essayist, was born in the parish of Halifax, Yorkshire, September 17, 1770. He was educated for the ministry at the Baptist College at Bristol, but after preaching for several years to various small congregations with very indifferent success, he resolved to devote himself mainly to literature. His *Essays, in a Series of Letters*, were published in 1805, while he was officiating as pastor of a Baptist chapel at Frome, in Somersetshire. They were only four in number—On a Man's Writing Memoirs of Himself; On Decision of Character; On the Application of the Epithet Romantic; and On some of the Causes by which Evangelical Religion has been rendered less acceptable to Persons of Cultivated Taste; yet Sir James Mackintosh did not hesitate to affirm that they showed their author to be 'one of the most profound and eloquent writers that England has produced.' They have been remarkably popular, especially among the more thoughtful of the community, and have gone through upwards of twenty editions.

In 1808, F. married the lady to whom his essays were originally addressed, and retired to Bourton-on-the-Water, in Gloucestershire, where he lived a quiet, studious, literary life, preaching, however, in the villages round about on Sundays. In 1819 appeared his celebrated *Essay on the Evils of Popular Ignorance*, in which he urges the necessity of a national system of education. He was long the principal writer in the *Eclectic Review*, and a selection from his contributions to that magazine was published by Dr. Price in 1844. He died at Stapelton, near Bristol, October 15, 1843. F. was a man of deep but sombre piety. The shadows that overhung his soul were, however, those of an inborn melancholy, and had nothing in common with the repulsive gloom of bigotry or fanaticism. His thinking is rugged, massive, and original; and at times, when his great imagination rouses itself from sleep, a splendor of illustration breaks over his pages that startles the reader both by its beauty and its suggestiveness. Besides the works already mentioned, F. published several others, of which the most important is an *Introductory Essay to Doddridge's Rise and Progress of Religion* (1825). Compare the *Life and Correspondence* of F. (2 vols. 1846), edited by J. E. Ryland, and republished in Bohn's Standard Library in 1852.

FO'THERGILL PROCESS. This is one of the numerous dry processes in Photography (q. v.) which have, for their object the preservation of sensitive plates ready for exposure. It is named after the inventor, and consists in the partial removal of the free nitrate of silver which adheres to the collodion film on withdrawing it from the sensitizing bath by washing with water, and the subsequent conversion of the remaining free nitrate of silver into albuminate and chloride of silver by pouring over the plate dilute albumen, containing chloride of ammonium, the excess of albumen being finally washed off by violent agitation with a copious supply of water. The plates being set aside to drain on folds of blotting-paper, are, when dry, ready for use. For details of manipulation, see handbooks of photography.

FOUCHÉ, JOSEPH, Duke of Otranto, the son of a sea-captain, was born at Nantes, 29th May 1763, and educated at the Oratoire. He hailed the Revolution with enthusiasm, and in 1792 became a member of the National Convention. He voted for the death of Louis XVI., and was one of the commissioners of the Committee of Public Safety sent to Lyon in 1794 to reduce that city to obedience. In 1795, he was expelled from the Convention as a dangerous Terrorist, and kept in confinement for a short time. After the revolution of the 18th Brumaire (5th November 1799), in which he took a part, F., as minister of police (an office to which he had been appointed on the 31st July of the same year), organized an extraordinary police. He restrained the new government from deeds of violence, and by his advice the list of *émigrés* was closed, a general amnesty proclaimed, and the principle of moderation and conciliation steadily adhered to. His remark upon the execution of the Duke d'Enghien was very happy: '*C'est bien pis qu'un crime, c'est une faute*' (It is much worse than a crime; it is a blunder).

In July 1804, he was again placed at the head of the police. His chief endeavors were directed, as before, to attaching the royalists to the imperial throne by prudent moderation. In 1809,

the Emperor conferred on him the title of Duke of Otranto, along with large grants from the revenues of the Neapolitan territory. When the English expedition landed on Walcheren (1809), the Emperor was absent, and F., who then held the portfolio of the interior, as well as of the police, organized the measures that led to the retirement of the English. In a proclamation issued on this occasion, he made use of a boastful expression which lost him the favor of Napoleon, and in the following year he was forced to resign. In the campaign of 1813, the Emperor summoned F. to headquarters at Dresden, and sent him thence as governor of the Illyrian provinces, and, after the battle of Leipsic, to Rome and Naples, in order to keep a watch upon Murat's proceedings. Being recalled to Paris in the spring of 1814, he predicted the downfall of Napoleon even before his arrival in France. After the Emperor's abdication, F. advised him to abandon Europe altogether. On his return from Elba, Napoleon again nominated him minister of police; but after the battle of Waterloo, F. placed himself at the head of the provisional government, brought about the capitulation of Paris, and drew back the army behind the Loire, thereby preventing unnecessary bloodshed. At the Restoration, Louis XVIII. reappointed him minister of police; but he resigned his office in a few months, and went as ambassador to Dresden. The law of the 12th January 1816, banishing all those who had voted for the death of Louis XVI., was extended to F. also, who from that time resided in different parts of Austria. He died at Trieste, 26th December 1820, leaving an immense fortune. Napoleon, at St. Helena, called F. 'a miscreant of all colors'; and Bourrienne declares that he 'never regarded a benefit in any other light than as a means of injuring his benefactor'—statements which are far too exaggerated to be worth much. The simple truth appears to be, that F. was a man whose highest principle was self-interest, but whose sagacity was not less conspicuous, and who never failed to give the governments which he served the soundest political advice. It is true, however, that he was unscrupulous in passing from one party to another, and that he was as destitute of political morality as Napoleon himself. In his private relations, the character of F. stands higher than in his public. As father of a family and as a friend he is worthy of all praise. He saved many a life; and harsh measures were often softened by his considerate administration. In 1824, appeared a work entitled *Mémoires de Fouché, Duc d'Otrante*, edited by A. Beauchamp, which, though declared to be spurious by the sons of F., is generally held to have been based on genuine documents.

FOUGERES, a handsome town of France, in the department of Ile-et-Vilaine, stands on a hill on the right bank of the Couesnon, 28 miles north-east of Rennes. It is a well-built town, with wide streets, and in the old quarter retains traces of the middle ages in the ancient arcades which still obtrude in some places upon the streets. The castle of F. is picturesque, but being commanded by other parts of the town, forms but a feeble defence. In the neighborhood is a great forest containing Druidical remains.

A famous engagement took place here between the Vendean royalists and the Republicans, November 15, 1793. F. has manufactures of sail-cloth, canvas, tape, flannel, lace, hats, &c.; and dyeworks, principally for the dyeing of scarlet. In the vicinity are important glass and paper-works. Pop. (1876) 10,396.

FOU'LA, or FOULAN, an island of Shetland, parish of Walls, from which it is distant 20 miles in a westerly direction. It extends 3 miles in length by $\frac{1}{2}$ in breadth, and rises to a height of 1369 feet above the sea. It is solitary, and with it there is no regular communication. F. has about 270 inhabitants, who subsist by fishing and farming on a small scale. On the island, there is a school maintained by the Society for Propagating Christian Knowledge; there is also a chapel connected with the Church of Scotland, and a chapel with a missionary maintained by the Congregational Union of Scotland. F. is chiefly remarkable for its sublime cliffs of red sandstone on its north-western side, where the precipice rises from the sea-margin to a height of nearly 1200 feet, being the grandest thing of the kind in the British Islands. Among the sea-birds which occupy the cliffs is the Skua Gull, or Bonxie (*Lestris cataractes*). Of this powerful bird there are about 13 pairs, which are prized by the natives for their services in keeping down the numbers of the eagles on the cliffs. The landing-place on F. is at a scattered hamlet of wretched thatched huts on the south-east. Here there is a store, at which imported commodities are bartered for fish and other articles, and at which an apartment is let to strangers, there being no inn. F. however, is rarely visited by strangers, and little is known of it even in Scotland.

FOULD, ACHILLE, was born in Paris on the 31st of October 1800, and was educated at the Lycée Charlemagne, one of the most celebrated establishments of Paris. He originally belonged to the Jewish creed, his family being wealthy Jew bankers, but he adopted the Protestant faith. Early in life, he was initiated into finan-

cial transactions by his father, and his natural talents were developed by travel in Europe and the East.

In 1842, he began his political career, being then chosen as a member of the council-general of the Hautes Pyrénées, and immediately after elected a deputy for Tarbes, the chief town of that department. He soon acquired a high position in the Chamber of Deputies for the peculiar talent with which he handled questions of finance and political economy. In 1844, he was appointed reporter to the commission on stamps on newspapers, and his views were adopted, in spite of the opposition party, he being at that period a staunch supporter of M. Guizot's home and foreign policy. After the revolution of 1848, F. accepted the new régime of the republic, and offered his services to the provisional government. In July 1848, he was elected representative for the department of the Seine, and continued to rise in public estimation by the elevated views he expressed in the chamber, while opposing among other things a proposed issue of assignats. During the presidency of Louis Napoleon, F. was four times Minister of Finance, and his repeated resignations for state reasons did not prevent him from being again appointed on the occasion of the *coup d'état*, 2d December 1851. He once more resigned his position on the 25th January following, in consequence of the decree ordering the confiscation of the property of the Orleans family. The same day, however, he was created a senator, and shortly afterwards returned to power as minister of state. In this capacity he superintended the Universal Paris Exhibition in 1855, the completion of the palace of the Louvre, and other great measures. He remained one of the most confidential ministers of Napoleon III. till December 1860, when he was succeeded as minister of state by Comte Walewsky. He was out of office up to the 14th November 1861, at which date he was reappointed finance minister, his long experience and well-known ability as a financier pointing him out as the man to manage the crisis of the French finances at that time. He died in 1867.

FOULIS, ROBERT and ANDREW, two eminent printers of Glasgow, brothers, whose names are usually classed together.—Robert, the elder, born in that city, April 20, 1707, was bred, and, like Allan Ramsay, for some time practised as a barber—in those days of flowing periwigs, a profitable and respectable profession. Having attended for several years the lectures of the celebrated Dr. Francis Hutcheson, then Professor of Moral Philosophy in Glasgow University, he was advised by that gentleman to become a bookseller. In winter, he and his brother Andrew (born November 23, 1712) employed themselves in teaching languages; and in summer, they made short excursions to the continent, and thereby acquired a considerable amount of learning and knowledge of the world. Andrew seems to have been designed for the church. In 1727, he entered as a student at the university of Glasgow, where he is supposed to have undergone a regular course of study. About the end of 1739, Robert began business in Glasgow as a printer, his first publications being chiefly of a religious nature. In 1742, he published an elegant edition in 4to of *Demetrius Phalereus on Elocution*, supposed to be the first Greek work printed in Glasgow. In 1743, he was appointed printer to the university. In 1744, he brought out his celebrated immaculate edition of Horace, 12mo, each printed sheet of which was hung up in the college of Glasgow, and a reward offered for the discovery of any inaccuracy.

Soon after, he took his brother Andrew into partnership; and for thirty years they continued to bring out some of the finest specimens of correct and elegant printing, particularly in the Latin and Greek classics, which the 18th c. produced, either in this country or on the continent. Among them were Cicero's works, in 20 volumes; Caesar's Commentaries, folio; Homer's works, 4 vols.; Herodotus, 9 vols., &c.; also an edition of the Greek Testament; Gray's poems; Pope's works; a folio edition of Milton, and other publications in English. With the view of promoting the cultivation of the fine arts in Scotland, Robert Foulis, after a two years' visit to the continent in preparation, commenced, in 1753, an academy at Glasgow, for the instruction of youth in painting and sculpture. The great expense attending this institution led to the decline of the printing business, which, however, continued to be carried on till the death of Andrew, September 18, 1775. In 1776, Robert exhibited and sold at Christie's, Pall Mall, London, the remainder of his paintings, when, after all expenses were defrayed, the balance in his favor amounted only to fifteen shillings. He died the same year at Edinburgh, on his return to Scotland. He was twice married, and left several children. One of them was a printer in Glasgow as late as 1806. His Virgil, printed in 1778, and his *Æschylus*, 1795, for beauty and exactness, were not unworthy of the name of Foulis.

FOUNDATION, This term may be applied either to the surface or bed on which a building rests, or to the lower part of the building which rests on the natural bed. 1. Foundation as the bed.—The best that can be had is solid rock, or any kind of re-

sisting incompressible stratum, free from water. Where there is no chance of water, sand forms a solid foundation. When the soil is soft, loose, and shifting, a solid bearing can be obtained only by driving *piles* or long beams of wood, sharpened at the end, through the soft soil, till they reach a hard bottom. This is then planked or laid with cross-beams, on which the superstructure is built. The piers of many bridges are formed in this manner. When the soil is soft, but not shifting, as in the case of made or deposited earth, the method of *Concreting* (q. v.) is adopted—i. e., a large surface is laid with broken metal or gravel, and run together with hot lime, so as to form a broad solid artificial rock, on which the building may rest. 2. Foundation as the base of the building.—The broader and larger the lower courses of the mason-work, the stronger the wall. The stones should, if possible, extend through and through, and project on each side of the wall.

In the best periods of art, the foundations have always been most attentively considered. The Romans formed solid bearings of concrete as above described, and paid great attention to secure the stability of their buildings. In the dark ages, when there was want of knowledge combined with want of materials and means, many buildings fell from the yielding of the foundations. Some of the earlier Gothic buildings also suffered from the same cause. But knowledge came with experience, and the foundations of the later Gothic buildings, during the 14th and 15th centuries, were built with extreme care, and on the virgin soil—the stones being as finely dressed as those above ground, where necessary to resist a strong thrust. And where the weight is thrown unequally on piers and walls, these detached points are all carefully united below the floor with a net-work of solid walls.

Bad foundations have been the cause of the ruin of many modern buildings. This has arisen from the costly nature of making a good foundation, when the soil is not naturally suitable. But it is clear that no expense should be spared to make the foundation good, as the value and stability of the superstructure depend entirely on the security of the foundation.

FOUNDER, also called LAMINITIS, consists of inflammation of the vascular sensitive laminae of the horse's foot. It is rarely met with in cattle or sheep, owing to the corresponding structures being in them greatly less developed. Occasionally, the laminae are strained from severe exertion; more frequently they suffer from the morbid effects of cold, which is especially injurious after the excitement and exhaustion of labor. Very commonly also, they become inflamed from their close sympathy with diseases of the digestive organs, often following engorgement of the stomach, or inflammation of the bowels. All four feet are sometimes affected, more usually the fore ones only. They are hot and tender; the animal stands as much as possible upon his heels; trembles and groans when moved; and is in a state of acute fever and pain. Except when following superpurgation or internal disease, bleeding is useful. The shoes must at once be removed, and the toes, if long, reduced, but no further rasping or cutting is permissible. The feet must be enveloped in hot bran poultices, and kept off the hard ground by a plentiful supply of short litter. Soap and water clysters, repeated if necessary every hour, usually suffice to open the bowels, which are very irritable, and physic, if required, must therefore be used with extreme caution. Two drachms of aloes is an ample dose in founder. Have the strain taken off the inflamed laminae by getting the animal, if possible, to lie down, or, where this is impracticable, by slinging him. When the inflammation continues so long that serum and lymph are poured out between the sensitive and horny laminae, they must have free exit provided, by making an opening through the toe with a small drawing-knife. This may prevent the *pumiced* and disfigured feet that are apt to follow severe and repeated attacks. After the acute symptoms pass, cold applications to the feet, and a mild blister round the coronet, help to restore the parts to their natural condition.

FOUNDING, or METAL-CASTING, is the art of obtaining casts of any desired object by means of pouring melted metal into moulds prepared for the purpose. It has risen to great importance in recent times, on account of the many new applications of iron. Iron-founding, brass-founding, type-founding, as well as casting in bronze and zinc, are the principal divisions of the art. The casting of the finer metals and alloys, as gold, silver, and German silver, is necessarily conducted on a smaller scale.

When the casting of an object is required, it is necessary, in the first place, to make a pattern. Suppose it to be a plain round iron pillar, such as is used for hanging a gate upon. A pattern of this is turned in some wood which can be readily made smooth on the surface, such as pine, and then varnished or painted so as to come freely out of the mould. This wooden pillar, or any similar pattern, is always made in at least two pieces, the division being lengthwise, for a reason which we shall presently see. The next step is to prepare the mould.

The moulds used by the iron-founder are either of sand or loam,

but more generally of fine sand. Proceeding with the preparation of the mould, the founder takes a moulding-box, which is composed of two open iron frames with cross-bars, the one fitting exactly on the other, by means of pins in the upper, dropping into holes in the lower frame. One-half of the box is first filled with damp sand, and the pattern laid upon it, a little dry *parting sand* being sprinkled on the surface. The upper half of the box is then put on, and sand firmly rammed all round the pattern. The box is then carefully opened, and, when the pattern is removed, its impression is left in the sand. The mould at this stage, however, is generally rough and broken. It is necessary, therefore, to give it a better finish, which is done by taking each half of the mould separately, repairing it with a small trowel, and re-introducing the corresponding half of the pattern till the impression is firm and perfect. Finally, the surface of the mould is coated with charcoal-dust, which gives a smooth surface to the future casting. These columns being made hollow, there is yet another matter to arrange before the casting can be made—namely, the *core*. In the instance before us, it would simply be a rod of iron, covered with straw and loam to whatever thickness the internal diameter of the column happened to require. The core of course occupies the center of the mould.

The cast iron is melted with coke in a round fire-brick furnace, called a *cupola*, the heat being urged by means of a powerful blast, created by fanners revolving at a high speed. The molten metal is run from a tap at the bottom of the furnace into a malleable iron ladle, lined with clay, from which it is poured into the mould through holes called *runners* or *gates*. When the mould is newly filled, numerous jets of blue flames issue from as many small holes pierced in the sand. These perforations are necessary for the escape of air and other gasses produced by the action of the hot metal on the mould. Care must also be taken not to have the mould too damp, otherwise steam is generated which may cause holes in the casting, and even force part of the metal out of the mould. The casting remains covered up for a time, in order to cool slowly, and is then removed by breaking away the sand, and drawing out the core.

In the case of a fluted, or otherwise ornamented pillar, the pattern would require to be in at least four pieces instead of two, because it is only a plain pattern that will come out of the mould in halves without tearing away the sand. When a pattern is necessarily made in several pieces, it is drawn out of the mould bit by bit, to the right or left, as the case may be, and so parts from the sand without breaking it.

Suppose that a small ornamental vase was to surmount the pillar, the founder would prepare the pattern of this in a more elaborate manner. He would first mould it in wax or clay, from which a cast in plaster of Paris is made; from that, again, a cast is taken in an alloy of tin and lead, which, after being sharply chased, and divided into the required number of pieces, is used as a pattern to cast from. All ornamented patterns, such as figures, scrolls, leaves, enriched mouldings, and the like, are made in this way, whatever metal the ultimate casting is to be produced in.

Very large engine cylinders, pans, and such vessels, are cast in loam-moulds, which are built of brick, plastered with loam, then coated with coal-dust, and finally dried by means of a fire. This method is adopted with large plain objects, where a pattern would be expensive, and when few castings of one kind are required.

Iron moulds, coated with blacklead or plumbago, have recently been introduced for casting pipes into; they are greatly more expensive than any other kind, but they enable the founder to dispense with a pattern, as, when once made into the required form, they are not destroyed like moulds of sand or loam at each casting.

Bronze and brass are cast in moulds prepared with finer sand than that used for iron. Pewter and similar soft metallic alloys are cast in brass moulds. The type-founder, on the other hand, uses moulds of steel, which are now worked to a great extent by a machine.

The variety of articles produced by founding or casting are very numerous, among others we may mention cylinders, cisterns, paper-engines, beams, boilers, pumps, and the heavy parts of machinery generally, gates, railings, lamps, grates, fenders, cooking-vessels, and the like, in iron; cannon, many portions of machinery, and numerous ornamental objects, in brass; sculpture and other works of art in bronze and the more costly metals. One of the most remarkable castings yet executed for the requirements of modern engineering, was the cylinder of the hydraulic press used for raising the tubes of the Britannia Bridge. It measured 9 feet $\times$ 3 feet 6 inches, the metal being 10 inches thick, and weighed upwards of twenty tons. It remained red hot for three days, and it was seven days more before men could approach it to remove the sand. Sole plates for steam-hammers, and for other purposes, have been cast more than double this weight, but the same care was not required in their execution. In regard to sculpture, perhaps the most wonderful casting known

is the colossal statue of Bavaria at Munich, finished in 1850, which stands 54 feet high, the face being equal to the height of a man. It took eight years to cast, and the cost of the bronze used was about £10,000.

FOUNDLING HOSPITALS, establishments in which children that have been abandoned by their parents and found by others, are nurtured at the public expense. Amongst the ancient nations, these institutions were not unknown, though as the law usually placed the power of life and death in the hands of the father, and permitted him to sell his children into slavery, it is to be feared that infanticide, as among eastern nations at the present day, was the usual mode of solving the difficulty which foundling hospitals are intended to meet. Desertion, however, and exposure as less atrocious, were still more frequent crimes; and to meet these, the reception and education of foundlings were enjoined on private persons, to whom they were assigned in property. When this means of support failed, they were protected by the state. The Egyptians and Thebans are praised by the classical historians for discouraging the exposure of infants.

The practice of exposing infants probably prevailed even amongst the Germanic nations previous to the introduction of Christianity; and though Tacitus says that infanticide was forbidden, in Iceland, in particular, it is said to have reached a fearful height. From the period at which Christianity became the state religion of the Roman empire, a sensible change in the spirit of legislation on the subjects both of infanticide and exposure is apparent; and though the latter is spoken of by Gibbon as one of the most stubborn remnants of heathendom, it gradually gave way, and the Christian church, at a very early period, lent its encouragement to the establishment of foundling hospitals. So early as the 6th c., a species of foundling hospital is said to have existed at Treves. The bishop permitted the children to be deposited in a marble basin which stood before the cathedral, and gave them in charge to members of the church. But the first well-authenticated one is that of Milan, established in 787, probably in obedience to the 70th article of the Council of Nice, which enjoined that a house should be established in each town for the reception of children abandoned by their parents. It is probable, however, that foundling hospitals existed pretty extensively at an earlier period, as mention is made of them in the capitularies of the Frankish kings. In 1070, a foundling hospital was established in Montpellier; in 1200, in Einbeck; in 1212, in Rome; in Florence, in 1317; in Nürnberg, in 1331; in Paris, in 1362; in Vienna, in 1380. In France, the utility of these establishments, which were the special labor of Vincent de Paul (q. v.), was early called in question; and letters-patent of Charles VIII., in 1445, affirmed that 'many persons would make less difficulty in abandoning themselves to sin when they saw that they were not to have the charge of the upbringing of their infants.' In Germany, the system of foundling hospitals was soon abandoned, the duty of rearing the children being, as in England, imposed by law, first on the parents, then on more distant relatives, whom failing, on the parish, and last of all, on the state. The reproach made by Roman Catholic countries against this more natural arrangement—that it tends to promote infanticide—is said to have been in no degree established by statistical investigations. The revolutionary government of France not only adopted the system of foundling hospitals, as it had been handed down to it, but in 1790 declared all children found to be children of the state (*enfants de la patrie*). Nay, as a still further premium on immorality, it declared that every girl who should declare her pregnancy should receive a premium of 120 francs! The imperial government in 1811, abolished this insane enactment, but continued and further systematized the arrangement by which the foundling hospitals had become government establishments, and the children, children of the state. This state of things remained unaltered till recently, and every considerable town had its foundling hospital and turning-wheel. The expense of rearing a child to the age of twelve in the hospital of Paris was computed at 952 francs, 42 centimes, or a trifle less than £40.

The moment that the child was received it was weighed, and if its weight was less than six pounds, it was considered that its chance to live was very small. It was then inscribed in a register, and a formal statement was drawn up of any name which had been given along with it, or of any particular mark which it bore either on its person or otherwise; of the hour at which it was deposited, its sex, and its dress. It was then inspected by a medical man, and handed over to the nurses. At Paris, each child was committed to a special nurse, many of whom were retained on the premises, and paid 40 centimes a day. Other nurses were brought in from the country in carriages kept by the Hospital, which returned conveying the children along with their new mothers. The children thus boarded out were inspected twice a year by local medical men appointed for the purpose. The parents and relations were permitted to reclaim them at any period, or they might be legally adopted by any French citizen in a condition to maintain them. A large proportion of the children were

not proper foundlings, but orphans and infants abandoned by parents unable or unwilling to bear the expense of their maintenance; and the mothers were known in many instances by offering themselves as nurses to get charge of their own infants. The question of the propriety of encouraging secrecy by the use of the turning-box, or of causing the parents openly to deposit the children in the hands of an officer, was long discussed with much keenness in France. The argument in favor of the turning-box was that by which the whole institution was defended, viz., that it tended to discourage infanticide. But even if that were unquestionable, there were many other obvious considerations to be taken into account, and these have preponderated. An official report by M. Gasparin, in 1837, showed that the number of children exposed had increased between 1811 and 1833, from 70,000 to 130,000; that the infant mortality was appalling; and that those who survived, ushered into the world without friends or means, constituted a large proportion of the thieves and prostitutes of the country. Within the last thirty years the whole system has been greatly modified, the changes being in the direction recommended in M. Gasparin's report. A large number of hospitals have been suppressed. The turning-box has been abolished, or, where retained, placed under such restrictions as make the abandonment public; the officers of the hospital, on receiving the infants, make full inquiry into the position and residence of the mother. The newborn infants have a separate department assigned them, and assistance is given at their own dwellings to mothers in circumstances to require it. The very name of 'enfants trouvés' has been exchanged for 'enfants assistés.' The result has been a vast diminution of the number of exposures, and a great saving of expense to the country, and lessening of mortality among the infants. The present number of foundling hospitals in France is believed to be about 130. In Spain they number about 70. Portugal, Belgium, Austria, and Norway possess foundling hospitals, and those of Moscow and St. Petersburg are among the largest in the world.

The Foundling Hospital in London was established by Captain Thomas Coram, a benevolent sailor, in 1739, as 'an hospital for exposed and deserted children.' The ground in Guildford Street was purchased from the Earl of Salisbury for £7000, and the architect of the hospital was Theodore Jacobson. The system of foundling hospitals never having been approved in England, the London hospital was changed in 1760 to what it is now—viz., an hospital for poor illegitimate children whose mothers are known. The committee, previous to admitting the child, must be satisfied of the previous good character and present necessity of the mother. The qualification for a governor is a donation of £50. The great Handel was one of the chief benefactors of the hospital. He endowed it with a magnificent organ, and frequently performed his oratorio of the *Messiah* in the chapel, which is still celebrated for its music. Though every attention is paid to the health and comfort of the children at the Foundling—to such an extent, indeed, as very often to unfit them for the hardships which many of them must encounter in after-life—we have been informed by the physician that they do not attain to the height of average English men and women. Foundling hospitals exist in Mexico, and in almost all the states of South America; in the United States there are few, and these mainly supported by private charity.

FOUNTAIN, a basin or jet for the supply of fresh running water. There are fountains of every form and variety, from the

Fontana Grande, Viterbo.

simple spring with its natural basin, to the most elaborate and ornamental structure for the display or supply of water. In all

ages, fountains have been considered as public monuments of the greatest importance; and where the source of their supply has not been provided by nature on the spot, immense labor and expenditure have often been incurred to make up for the deficiency. The splendid Aqueducts (q. v.) of the Romans are instances of the important light in which they regarded the fountains of their cities. Every Roman town had at least one aqueduct, the water from which was distributed to as many fountains as the population required.

Utility is the first object of a fountain, and although they are frequently made subjects of great display and magnificence, the finest fountains are those where the water is the greatest ornament. In the middle ages, fountains of great beauty and variety of form were built, but the useful nature of the structure was never lost sight of. Sometimes a spring was arched over for protection, with a beautiful vault, and a statue of the patron saint placed in a niche, with a basin below to contain the water. In towns where a number of persons might require to draw at one time, a large basin was erected, with a pillar in the center, from which pipes radiated all round—each with its separate jet to supply the running water—while the basin was used for washing the pitchers. Many examples of this kind of fountain remain. On page 271 is represented a fountain at Viterbo, in the former Papal States, where there are many of the same description. The pillar is sometimes surmounted by a statue, or has one or more smaller basins, with ornamental streams and jets of water falling from tier to tier. A beautiful fountain of this nature existed in the royal palace at Linlithgow, and a copy of it has been erected in front of Holyrood Palace.

In modern times, the French have distinguished themselves by their magnificent fountains, those of Paris and Versailles being almost unrivalled. In England, the fountains at Chatsworth (q. v.) and those at the Crystal Palace are among the finest, and are remarkable for the great height to which the water is thrown. Although Rome has lost four-fifths of the aqueducts which so lavishly supplied her with fresh water in the times of the Empire, she is still unsurpassed for the number, beauty, and utility of the public fountains which adorn her streets and places.

Modern fountains are, for the most part, entirely ornamental. This arises from the modern mode of distributing water in pipes through the houses, making the street-fountains to a great extent useless. It is found, however, that our town populations—both man and beast—require some public supplies of water, and these are now largely supplied by the numerous drinking-fountains which are being constructed in all our principal towns.

FOUNTAIN. Water is represented heraldically by a round ball, having waving stripes of blue and white, barways, called a fountain.

FOUQUÉ. **FRIEDRICH HEINRICH KARL, BARON DE LA MOTTE**, a modern German author, was grandson of the Prussian general of this name, distinguished in the Seven Years' War. Born at Brandenburg, 12th February 1777, served as Prussian officer in the campaigns of 1792 and 1813. The interval between these campaigns was devoted to literary pursuits in the country, and the rest of his life was spent alternately in Paris and on his estate at Nennhausen, and subsequently at Halle. He died in Berlin, 23d January 1843. F. appeared first under the name Pellegrin, as translator of Cervantes's *Numancia*, and author of some effusions in the spirit of Spanish poetry. But the Norse legends and old German poetry attracted him most strongly; this was evinced in numerous romances, in prose and verse, which picture the old life of medieval Europe. Among the best known of these are *Sigurd, der Schlangentöchter* (1809)—the first work to which F. attached his real name—*Der Zauberring, Die Fahrten Thiodolfs* and *Undine*.

Successful in exhibiting many of the beauties of the romantic school, he is yet chargeable with all its extravagances. Straining too often after fantastically unnatural conceits, he seems fascinated by the antique life which he pictures, rather merely from its quaint contrast with modern manners, than as a form into which the life of actually living men had shaped itself in former times. He himself edited a selection of his works (*Auserwählte Werke*, 12 Bde., Halle, 1841).—F.'s first wife, **KAROLINE VON BRIEST**, is also known in Germany as a productive authoress.

FOQUIER-TINVILLE, ANTOINE QUENTIN, the notorious public accuser in the French Revolution, was born in the village of Hérouelles, in the department of Aisne, in 1747. His early career was immoral, but insignificant. On the outbreak of the Revolution, he figured as one of the fiercest democrats. By Robespierre, he was appointed, first, a member, then director and public accuser, of the Revolutionary Tribunal. Without education, conscience, or sense of justice, he executed with brutal apathy the bloody orders of the Committee of Public Safety. In reference to this feature of his character, his countrymen say that 'he had no soul—not even that of a tiger, which at least pre-

tends to be pleased with what it devours.' Incapable of friendship, or of anything even remotely allied to generosity, he systematically abandoned his coadjutors in their hour of need, and sent to the scaffold, without the slightest compunction, Bailly and Vergniaud, Danton and Hebert, Robespierre and St. Just. He himself died by the guillotine, in a cowardly manner, 7th May 1795.

FOUR EVANGELISTS, part of a larger group of islands known as the *Twelve Apostles*, lie off the west entrance of the Strait of Magellan. They are about lat. 52° 34' S., and long. 75° 5' W. The eight other islands, with which they are classed as above, run about 15 miles further out into the Pacific.

FOUR LAKES, a chain of connected sheets of water in Wisconsin, United States, are fed chiefly by springs, and form, through their outlet, the Catfish, a north-eastern source of the Mississippi. They are navigable for steam-boats, and drain a beautiful country. Madison, the capital of the state, stands on the strip of land which separates the uppermost of the series from the next in order.

FOURCHAMBOULT, a rapidly increasing town of France, in the department of Nièvre, five miles north-north-west from Nevers, near the right bank of the Loire, which is here crossed by a suspension bridge. It is a station on the railway between Orleans and Nevers. There are great iron-foundries, employing between 2000 and 3000 workmen. The manufacture of arms is extensively carried on. Pop. (1876) 5686.

FOURCRO'YA, a genus of plants of the natural order *Amaryl-lidææ*, nearly allied to *Agave* (q. v.), but with stamens shorter than the corolla. The species are all tropical. The leaves of some—perhaps of all—of them yield a fibre similar to the *PITA FLAX* obtained from those of species of *Agave*.

FOURIER, JEAN BAPTISTE JOSEPH, BARON, a distinguished French mathematician, was born of a respectable family at Auxerre, 21st March 1768. He became a pupil, and at the age of 18, a professor, in the military school of his native place. He was afterwards removed to the normal school in Paris, and then to the Polytechnic, and accompanied General Bonaparte to Egypt. Besides performing political services on this occasion, he was secretary to the *Institut d'Egypte*, and an active contributor to the *Description de l'Egypte*, the masterly historical introduction to which is from his pen. On returning to France, he was made préfet of the department of Isère in 1802, an office which he held till 1815, and was created baron in 1808. As préfet, he succeeded in draining the marshes in Bourgoin, near Lyon, which had for centuries baffled all attempts. On the return of Napoleon from Elba, F. issued a royalist proclamation; notwithstanding which he was appointed by Napoleon préfet of the department of the Rhone, but was shortly after removed. He now took up his abode in Paris, and devoted himself exclusively to science. The Academy of Sciences, which in 1807 had crowned his essay on the propagation of heat through solid bodies, chose him a member in 1815, and afterwards secretary for life, conjointly with Cuvier. He died 16th May 1830.

His most famous work is the *Théorie Analytique de la Chaleur* (Par. 1822), in which he applies new methods of mathematical investigation. An allied subject is discussed in his *Mémoire sur les Températures du Globe Terrestre et des Espaces Planétaires* (Par. 1827). Besides heat, he occupied himself with the theory of equations, which received from him important improvements. His work, *Analyse des Equations Déterminées*, distinguished both for its substance and manner of exposition, was left unfinished and was published after his death by Navier (Par. 1831).

FOURIER, FRANÇOIS MARIE CHARLES, a French Socialist, was born at Besançon, April 7, 1772. His father, a merchant, had him educated in an academy at Besançon for his own profession. He distinguished himself by his perseverance and success in study, and excelled in geography, mathematics, music, and the natural sciences. He left his studies with regret to enter upon the duties of a merchant's clerk, which he performed with zeal and integrity at Lyon, Rouen, Marseille, and Bordeaux. He also traveled in the interest of his employers, not only in France, but in Holland and Germany. In these journeys and residences, nothing escaped his observation; he noted climate, culture, population, public and private edifices, and remembered even the topography of villages, and the dimensions of buildings, with astonishing accuracy. His father died in 1781, leaving him about £5000, which he became possessed of in 1793, and invested in trade at Lyon. This was lost in the Revolution; and he was thrown into prison, and compelled to serve two years as a cavalry soldier. Discharged on account of illness, he obtained employment in a mercantile house at Marseille, where he was employed to superintend the destruction of an immense quantity of rice, held for higher prices, in the midst of a scarcity of food, until it had become unfit for consumption. This circumstance called his attention to the frauds and duplicities of commerce, and he devoted his spare time to the

study of social problems, until he developed the system of Socialism to which his name is commonly given. This system is contained in several works, written and published under discouraging circumstances.

In 1808, he published his *Théorie des Quatre Mouvements, et des Destinées Générales* (Theory of the Four Movements, and of the General Destinies of the Human Race). In 1822, he produced his *Traité d'Association Domestique Agricole* (Treatise on Domestic and Agricultural Association); in 1829, *Le Nouveau Monde Industriel et Social* (The New Industrial and Social World); in 1831, *Pièges et Charlatanisme des Deux Sectes Saint-Simon et Owen, promettant l'Association et Progrès* (Snares and Quackeries of the Two Sects of St. Simonians and Owenites, promising Association and Progress); in 1835, *La Fausse Industrie, Morcelée, Répugnante, Mensongère, et l'Antidote, l'Industrie, Naturelle, Combinée, Attractive, Véridique, donnant Quadruple Produit* (False Industry, Fragmentary, Repulsive, and Lying, and the Antidote, a Natural, Combined, Attractive, and Truthful Industry, giving Quadruple Products.) These works, written in the midst of commercial pursuits, and published at long intervals, by means of his small savings, found for many years few readers, and no disciples. Towards the close of his life, a small group of intellectual men accepted his views, and gathered round him, to learn the details of his social system from his own lips. He was unwearied in his efforts to interest men of power or capital, who could give his theories the test of practical realization, and for many of the last years of his life waited patiently at a certain hour every day, expecting to be visited by such a patron. His less patient disciples probably hastened his death by immature and partial efforts at realization. He died in Paris, October 8, 1837.

FOURIERISM, the Social System invented by Charles Fourier, is contained in his published works, in a large collection of unpublished MSS., and in the writings of Considerant, Lechevallier, Brisbane, and others of his disciples. It differs materially from the systems of Communism strictly so called, and all other social theories, and professes to be based upon natural laws, and capable of being carried out on mathematical principles, as certain as those of geometry, music, or colors. The earth and human society, Fourier taught, are in their crude and infantile stage. The period of the race will be 80,000 years, the latter portion of which will be its declining phase, as the present is its ascending. The middle term will be a long period of maturity, prosperity, and happiness. What we call civilization, Fourier considers a false and imperfect condition, with poverty, crime, ignorance, idleness, repugnant toil, disease, wasting wars, general antagonism, oppression, and misery. He believed that Association would produce general riches, honesty, attractive and varied industry, health, peace, and universal happiness. Considering attractions and repulsions the governing forces of all nature, and that God has distributed them for the happiness of all His creatures, he held that 'attractions are proportional to destinies,' or that the desires or passions of men, their aptitudes and inclinations, if they could have free scope, would infallibly produce the highest condition and greatest happiness of which they are capable. He believed in a universal harmony, flowing from and centering in God, the author of all harmonies, and that there is therefore a principle of 'universal analogy.'

Seeing that all things, from suns and planets to atoms, range themselves in groups and series, according to certain fixed laws of attraction and repulsion, he labored to discover the kind of human society that must eventually form itself in obedience to those laws. This is the Association or Phalanstery, which is to consist of 400 families or 1800 persons, which number he found included the whole circle of human capacities. These should live in one immense edifice, in the center of a large and highly cultivated domain, and furnished with work-shops, studios, and all the appliances of industry and art, as well as all the sources of amusement and pleasure. When the earth is covered with palaces of attractive industry, the associations will also unite in groups and series, under a unitary government. There will be but one language and one government, and the only armies will be the great industrial armies, which will drain swamps, irrigate deserts, plant forests, and effect the amelioration of climates. The system of Fourier does not propose to destroy, but rather to conserve property, position, and hereditary rights, nor does it war directly with morals or religion. The property of the Association is to be held in shares, and the whole product of the industrial and artistic groups is to be divided into twelve parts, of which five parts are due to labor, four to capital, and three to talent. The apartments are to be of various prices, and the styles of living to vary in luxury and cost; but the poorest person in the Association is not only to be secure of comfort, but his minimum of enjoyments will be greater than the present social arrangements can give to princes and millionaires; while these will have opened to them pleasures of which they can now scarcely have a conception. The economies of the large scale in the Phalanstery reduce by two-thirds

the expenses of living, while an attractive and scientific industry would quadruple the products of civilization.

The passions of the human soul to which the system of Fourier would give full scope, he described as the five sensitive—sight, hearing, taste, smell, touch; four affective—friendship, love, ambition, and paternity; three distributive—the emulative, alternating, and composite. In these he found the springs of industry and true society. Emulation, the desire of success, honors, rewards, is the great stimulant to exertion; alternation of employments makes work a recreation; and the composite passion requires combinations of charm and enjoyment which only Association can give. Many attempts have been made—a few in France, and more in America—to carry the ideas of Fourier into practical realization; but they have all been on a small scale, and with inadequate means, and have resulted in failure. Whatever we may think of the system, in its principles or its theoretical development, nothing can be founded upon the failure of such experiments. It remains to be proved whether human nature, in its present state, is capable of carrying out successfully a social system so widely varying from all existing social conditions. The moral objections to Fourierism are, that it appears to make luxury, ambition, and sensual delights the end of existence—the incentives and rewards to all exertions; and that the passions of men, when left in the perfect freedom which this system requires would lead to ruinous demoralizations. The answer is, that 'attractions are proportional to destinies,' and that these excesses belong to the present state, and are incident to the poverty and repressions of civilization, but could not exist in a true society; which raises the question—What is a true society? Whatever may be thought of the practicability of the system, its study in the works of Fourier is full of suggestions to the student in sociology.

FOURNI ISLANDS (anc. *Corássiæ* or *Córseæ*), a group of about 20 small islands in the Grecian Archipelago, between Nicaria and Samos, on the eastern coast of Asiatic Turkey. The largest of these islets is about five miles in circuit.

FOWEY, or FOY, a borough town on the south coast of Cornwall, on the right bank of the river Fowey, 25 miles south-south-west of Launceston. It is sheltered by hills, and lies amid picturesque scenery, rude sea-cliffs, and promontories. The harbor admits large vessels at all states of the tide, and its entrance is guarded by three forts. The chief business is catching and curing pilchards, which, with 'china-stone' and iron-ore, form the main exports. F. sent 47 ships and 770 men to the siege of Calais by Edward III. in 1347. It was burned by the French in 1457, and taken by Fairfax in 1646. Pop. (1881) 1656.

FOWL (Ger. *vogel*; allied to the Lat. root *fug-*, to flee, and perhaps to *vag-*), a word originally synonymous with *bird*, and still employed in that signification, but also in a much more restricted sense, as the designation of the genus of Birds (*Gallus*) to which the common Domestic Fowl (*G. domesticus*) belongs. This genus gives its name to the important order of *Gallinaceous Birds*, also called, from their well-known habit of scraping the earth in search of food, *Rasores* (Lat. Scrapers); and is included in the family *Phasianidæ*, with pheasants, tragopans, &c. The general form, and the characters of the bill, feet, &c., agree with those of the pheasants; but the crown of the head is generally naked, and furnished with a fleshy *comb*, the base of the lower mandibles also bearing fleshy lobes or *wattles*, characters which are most conspicuous in the males; and the tail is very different from that of the pheasants, and, indeed, very singularly formed, being composed of fourteen feathers in two nearly vertical planes, or as if a horizontal tail were folded together, so as to make a sharp angle at top, the two middle feathers being the uppermost, and in the males elongated beyond the rest, and gracefully arched. The tail-coverts of the male are also very ample, and the feathers of the back of the head and of the neck are either elongated and loosely webbed, forming the *hackles*, so much valued by anglers for dressing artificial flies, or are otherwise modified to serve the purpose of adornment; characters which are also sometimes exhibited in a very inferior degree in the female sex. The legs of the male are armed with spurs, as in the pheasants, of which much use is made in the combats of these birds among themselves, all of them being very pugnacious. They are all polygamous, and unable to endure the presence of a rival. They are all natives of the East Indies and of the Malayan Archipelago. From what country, and at what period the Domestic Fowl was originally introduced into Europe, is uncertain. The remains of Egyptian antiquity carry us back to a period when it was apparently unknown in Egypt, and there is no distinct allusion to it in the Old Testament; but it seems to have been common in the south of Europe from the earliest ages of European civilization.

The cock was sacred to Apollo, to Mercury, to Mars, and to Æsculapius. It was figured on Grecian and Roman coins and gems; it was highly valued for its courage and pugnacity, and the sport of cock-fighting was a favorite one both with the Greeks and the

Romans, as it is amongst the Chinese, the Malays, and many other nations at the present day, and in former times was amongst all classes of society even in Britain. See **COCK-FIGHTING**. The Domestic Fowl appears to have been known to the ancient Britons before the Roman invasion; and when the South Sea Islands were first visited by Europeans, it was found there in the same domesticated state, and there also cock-fighting was found to be a fashionable amusement of the savage natives. The native country of the Domestic Fowl is not certainly known, nor is it certain what the species is in its original state. The ancient Greeks sometimes called it the *Persian Bird*, and hence it has been supposed to be a native of Persia; but there is nothing else to support this opinion, and it seems likely enough that this appellation may at most only indicate its introduction into Greece from Persia. The Jungle Fowl of India, the first species of *Gallus* known in its wild state to naturalists, was for some time supposed to be the origin of the Domestic fowl, but to this opinion there are strong objections in the very peculiar character of some of the feathers which distinguish the Jungle Fowl, and of which no trace ever appears in the Domestic Fowl. More recently, the Bankiva Fowl and other species have been discovered in Java and other islands of the Eastern Archipelago, more nearly resembling the Domestic Fowl, and the distribution of the latter through the islands of the Pacific Ocean is favorable to the belief that it derived its origin from that region; but still the identification of the species remains difficult, and some naturalists incline to the opinion that the Domestic Fowl may be derived from intermixture of distinct wild races.

The **BANKIVA FOWL** (*G. Bankiva*), native of Java, is extremely similar to some of the domestic varieties; indeed, Sir William Jardine says: 'Many Bantams so nearly resemble this bird, that there would be great difficulty in making a distinction. The comb is large and lobed, or dented; the colors are brilliant, steel-blue and chestnut, black and yellowish brown, the hackles abundant and golden orange; some parts of the plumage exhibiting a very fine play of colors. A very similar species, or a variety of the same, but rather larger, is found in some parts of continental India.' Very similar also is the **BRONZED FOWL** (*G. aneus*), found in Sumatra, a bird resplendent in metallic green, purple, and lake; but of which the comb has the upper margin unbroken; the wattles are combined into one attached to the center of the throat; and the neck feathers do not assume the *hackle* character, which appears in the neighborhood of the tail alone. These peculiarities also belong to the **FORK-TAILED FOWL** (*G. furcatus* or *Javanicus*), a species very abundant in the jungles of Java, and often to be seen on their outskirts, nearly two feet in length from the tip of the bill to the extremity of the tail.

A still larger species—if, indeed, these are not rather varieties than species—is the **GIGANTIC FOWL**, **JAGO FOWL**, or **KULM FOWL** (*G. giganteus*) of Sumatra, with the double wattle under the throat, abundant hackles on the head, neck, and upper part of the back, green and reddish yellow the principal colors, and the height considerably more than two feet.—The **JUNGLE FOWL** (*A. Sonneratii*), abundant in the higher wooded districts of India, where it is much sought after by European sportsmen, is about equal in size to an ordinary Domestic Fowl, but is more slender and graceful in its form; the comb of the male is large, and its margin broken; the colors are rich and beautiful; but a remarkable peculiarity is exhibited in the hackle feathers, which are terminated by flat horny plates of a golden orange color, into which the shaft expands, or the shaft thickening and terminating abruptly gives rise to a battledore-like stem and disc, in substance like the tips of some of the feathers of the wax-wing.

Of the Domestic Fowl there are some very curious varieties, of which some naturalists have attempted to constitute distinct species, particularly the **NEGRO FOWL** (*G. morio*), rarely seen in British poultry-yards, remarkable for the black color of the *periosteum* (the outer covering of the bones), and the dull purple of the comb, wattles, and skin; the **SILKY FOWL** (*G. lanatus*), very common in China and Japan, with periosteum and skin of the same dark color as the Negro Fowl, but the flesh remarkably white, the comb and wattles purple, the feathers with webs disunited and silky; and the **FRIESLAND** (probably a mistake for **FRIZZLED**) **FOWL** (*G. crispus*), which has all the feathers standing nearly at right angles to the body.

There are also varieties of the Domestic Fowl remarkable for what may be considered monstrosities—as the want of a tail and of some of the last vertebrae, the presence of an additional spur on each leg (Dorkings, &c.), superabundant combs, crests or tufts of hackle feathers instead of combs, tufts of feathers springing from the lower jaw (the **SIBERIAN FOWL**), &c; and there are many varieties esteemed by keepers of poultry, of which the most important are—1. The **GAME FOWL**, with erect and slender body and showy colors, valued also for the delicacy of the flesh and of the eggs, although the eggs are rather small. It is this breed which is used for cock-fighting; and so excessive is the pugnacity which characterizes it, that broods scarcely feathered are occasionally found to have reduced themselves to utter blindness by

their combats. Some poultry-keepers think it good to have a game-cock in their poultry-yard, on account of the improvement of the quality of the fowls sent to the table; but it is almost needless to say, he must, like the prototype of Robinson Crusoe, be sole monarch of all he surveys. 2. The **DORKING FOWL**, so named from Dorking, in Surrey, where it has long been bred in great numbers for the London market—a breed characterized by an additional spur on each leg; often of a white color, with short legs; one of the most useful of all breeds, both for excellence of flesh and for abundance of eggs. 3. The **POLISH FOWL**, black, with a white tuft, a breed very extensively reared in France, Egypt, &c., little inclined to incubation, but valued for an almost uninterrupted laying of eggs.

4. The **SPANISH FOWL**, very similar to the Polish, but larger, and laying larger eggs, on account of which it is now much valued, and very common in Britain; black, with white cheeks and large red comb. 5. The **MALAY FOWL**, tall and handsome, very pugnacious, but little esteemed. 6. The **HAMBURG**, of very beautiful plumage, and much valued for the quality both of flesh and eggs, as also for extreme productiveness of eggs. 7. The **COCHIN CHINA FOWL**, a large, tall, ungraceful variety, with small tail and wings, for which there was a great rage among poultry-fanciers when it was newly introduced into Britain, and particularly about the year 1852, and which is valuable chiefly on account of its fecundity, eggs being laid even during winter, and the hens incubating frequently. 8. The **BANTAM FOWL** (q. v.), a diminutive variety, rather curious than useful.—Of most of these there are many sub-varieties and *fancy breeds*—gold-penciled, silver-penciled, &c. The common **DUNGHILL FOWL** is apparently a breed produced by the intermixture of others, and perhaps chiefly a less graceful, less spirited, and less pugnacious race of the Game Fowl.

Concerning the treatment of the Domestic Fowl in the poultry-yard, the diseases to which it is liable, &c., see **POULTRY**. The artificial hatching of eggs is noticed in the article **INCUBATION**. Concerning the eggs of the Domestic Fowl as an article of commerce, &c., see **EGG**.

The readiness with which the Domestic Fowl can be induced to go on laying eggs beyond the number proper for a brood, is not nearly equalled in the case of any other domesticated bird, and greatly enhances the usefulness of this species to mankind, whether the eggs are used for food, or, by artificial hatching, made to produce chickens, as is common in Egypt and some other countries. Few hens incubate oftener than once a year, but some lay in the course of a year even more than 200 eggs.

FOWLER'S SOLUTION. See **ARSENIC**.

FOWLING—the killing or taking of birds for the sake of their flesh, feathers, &c.—is very variously practised in different parts of the world. In some places it is one of the principal employments of the people, who greatly depend on it for their subsistence, and prosecute it with the greatest toil and danger; elsewhere, it is in some of its forms a recreation, for the sake of which much expense is incurred by the opulent. The modes in which it is practised depend partly on the habits of different kinds of birds, and partly on the progress of civilization and the arts. The peculiar habits of some birds render it very easy to take or kill them. Nets are much used in the capture of many kinds of birds, particularly of small birds intended for the table: bird-lime is employed for the same purpose, and birds are taken by means of it in greatest numbers near their drinking-places, particularly in hot and dry weather; gins, springs and traps of various kinds are also employed.

The numerous kinds of ducks, geese, and other *Anatidæ*, are, in an economical point of view, among the most important of birds; and the methods employed for their capture are very various and interesting. These, however, we reserve for a separate article, **WILDFOWL**; and refraining also here from any notice of the amusements of the sportsman, we shall proceed to describe the methods adopted in *Rock-fowling*, on which the inhabitants of many northern coasts and islands in a great measure depend for their means of subsistence.

Of all kinds of fowling, it is by far the most adventurous. The objects of pursuit are gannets or solan geese, gulls, terns, guillemots, and other sea-birds, which frequent the most lofty precipices, and breed on their shelves and ledges. The flesh, even of the best of them, is generally coarse, and of a fishy taste, yet it forms great part of the food of the poor people, both fresh, and salted for winter provisions. The flesh of the young is more tender and pleasant than that of adult birds. The eggs of some species are sought after by the same perilous means as the birds themselves. The feathers and oil are articles of commerce. The people of St. Kilda pay part of their rent in feathers and fulmar oil, the rocks being apportioned among its inhabitants as exactly as its soil. Almost every man in the island is a cragsman or rock-fowler, which is pretty nearly the case also in many northern isles. The multitudes of sea-fowl around many of the rocky northern coasts

is prodigious, resembling at a distance—as may be seen at the Bass Rock in the Firth of Forth—the bees around a busy hive. Uninhabited islets are annually visited by fowlers, as Borrera by the people of St. Kilda; and the 'stacks,' or high insular rocks near the shore, are often extremely productive. These are, of course, reached by means of a boat; and whilst landing is often both difficult and dangerous, the climbing of the precipice is still more so. The Norwegian fowlers, or 'bird-men,' carry on such expeditions with a *bird-pole* or *fowling-staff*, about five or six yards long, and a rope of several fathoms. The bird-pole has an iron hook at one end; it has also a flat head; and by means of it the fowler is pushed and guided by his comrades below as he ascends a very steep or precipitous cliff; by means of it, also, he strikes down or draws in birds. The rope is used to fasten two fowlers together, being attached to the waist of each; they aid one another in climbing, pushing, and drawing one another up the rocks, the safety of the one often depending on the strength and courage of the other. The bird-pole is also used with a small net attached to it, in the capture of birds that are flying around. The Norwegian fowlers sometimes remain for days on ledges where birds are abundant, sleeping in holes or clefts, and having food let down to them by a rope from above.

Still more perilous, if possible, is the mode of fowling practised where the precipices cannot be scaled. The fowler is let down by a rope, and hangs in mid-air, often at an elevation of several hundred feet, above rough rocks or roaring waves; and by means of his feet or of a pole, throws himself out to such a distance from the face of the rock as to obtain a view of all its ledges and cran-

The Holm of Noss, Shetland.

nies, to which with astonishing coolness and dexterity, he directs his course, often also catching the birds that fly near him in the air. Speaking of the fowlers of St. Kilda, Wilson (*Voyage Round the Coast of Scotland and the Isles*) remarks: 'How one man (for such is the case), himself standing with the points of his toes upon the verge of a precipice many hundred feet deep, can, with such secure and unerring strength, sustain the entire weight of another man bounding from point to point below him with irregular and frequent springs, is what a stranger cannot understand. . . . But we ascertained that there is never more than a single man above supporting the weight of the one below.'

Each of these couples has two ropes. The rope which the upper man holds in his hands is fastened round the body and beneath the arms of him who descends, while another rope is pressed by the feet of the upper man, and is held in the hand of the lower. The second rope is for giving signals, and for sending up birds when captured. The principal rope used to be made of twisted raw cow-hide; it was so durable as to last for two generations, and was bequeathed as valuable property by father to son. Manilla hemp is now chiefly used instead. The practice differs also as to the number of comrades holding the rope above. In the Faroe Isles, where some of the precipices are 1400 feet in height, the rope is usually held by a number of men. In some of the Scottish islands, fowlers have been adventurous enough to descend the cliffs unaided, fastening the rope for themselves to a stake driven into the ground above. The fowlers of the Faroe Isles sometimes use the pole with net at the end, whilst suspended in the air. It is not unusual for the fowler, when he finds a ledge or recess in the precipice abounding in birds, to disengage himself from the rope whilst he pursues his labors there; but when the precipice overhangs above, he is exposed to a great danger of the rope's escaping from his reach. A case is on record in which the only resource of the fowler was to make a desperate

spring and catch the rope, which hung a few feet before him in the air; and this he succeeded in doing.

The cut represents rock-fowling at the Holm of Noss, a precipitous insular rock, separated from Noss, one of the Shetland Isles, by a chasm of 65 feet wide, and 160 feet deep, over which ropes have been stretched, so that a *cradle* or sparr'd box can be made to pass along them, affording access to the grassy summit of the Holm, where a few sheep are occasionally fed, and where innumerable sea-birds make their nests.

FOWLS OF WARREN. Lord Coke says they are 'the partridge, quail, rail, &c.,' 'pheasant, wood-cock, &c.,' and the 'mallard, heron, &c.,' leaving the ceteras without explanation (*Co. Litt.* 233). Manwood, again, lays it down that there are only two fowls of warren, the pheasant and the partridge (*Manw.* 95). In the Duke of Devonshire v. Lodge (7 B. and C. 36), it was decided that grouse are not birds of warren.

FOX, CHARLES JAMES, a celebrated Whig statesman, was the second son of Henry Fox, first Lord Holland, by Lady Georgiana Carolina, eldest daughter of the Duke of Richmond. He was born, according to Lord John Russell's memoir, on the 24th January 1749 (N.S.), and was educated at Eton and Oxford, spending his vacations on the continent in the gayest wittiest circles of the French capital, and visiting Switzerland and Italy. Notwithstanding the irregular life which he led even as a school-boy, he was very distinguished for ability both at school and college; and so high was his father's opinion of his talents, that at the age of nineteen he had him brought into parliament as member for the borough of Midhurst, a step to which he is said to have been further incited by the fact, that, even at this early age, F.'s energies had found an outlet in gambling and various other forms of dissipation. His precocity in vice, as well as in intellectual development, is said to have been the result of the injudicious fondness of his very unprincipled but very gifted father. Till he attained his majority, F. prudently kept silent in the House, but immediately thereafter he appeared as a supporter of the administration of Lord North, and was rewarded with the office of one of the lords of the Admiralty. In 1772, he resigned that office, and the following year was named a commissioner of the Treasury. From that post he was dismissed, in consequence of a quarrel with Lord North, and passed over to the ranks of the opposition. During the whole course of the American war, he was the most formidable opponent of the coercive measures which were adopted by the government, and the most powerful advocate of the claims of the colonists; acting, to this extent at least, in accordance with the views which for many years before had been urged upon the country by the great Lord Chatham, the father of his future rival Mr. Pitt. The difference between them was, that whereas Lord Chatham urged conciliation, in order to preserve the connection between the two countries, F. foresaw and foretold the necessity and the advantages of complete separation. In 1782, on the downfall of Lord North, F. was appointed one of the secretaries of state, which office he held till the death of the Marquis of Rockingham, when he was succeeded by the Earl of Shelburne, afterwards Marquis of Lansdowne. On the dissolution of the Shelburne administration, the North and Fox coalition was formed, and F. resumed his former office; but the rejection of his India Bill by the House of Lords soon after led to the resignation of his government. It was now that Mr. Pitt came into power, and that the long and famous contest between him and F., who occupied the position of leader of the opposition, commenced. In 1788, he enjoyed a short respite from his public labors. Accompanied by his wife, he visited the continent, and having spent a few days at Lansanne, in the company of Gibbon, who was there engaged in writing his famous history, he set out for Italy. The sudden illness of the king, however, and the necessity of constituting a regency, rendered it undesirable that he should be longer absent from England, and he hastened back to his post.

The regency, the trial of Warren Hastings, the French Revolution, and the events which followed it, gave ample scope to the talents and energies of F., and on all occasions he employed his influence to modify, if not to counteract, the policy of his great rival. He was a strenuous opponent of the war with France, and an advocate of those non-intervention views which find greater favor in our day than they did in his. After the death of Pitt, F. was recalled to office, and endeavored to realize his doctrines by setting on foot negotiations for a peace with France, the results of which he did not live to witness. He died on the 13th September 1806, in his 59th year. In private life, Mr. F. was a genial companion, kindly and sincere in the closer relations of friendship, whilst his conduct to those to whom he was opposed in public was generous, and free from every trace of malignity or enmity. Lord John Russell, in his preface to his *Memorials and Correspondence*, speaks of the singular candor, boldness, simplicity, and kindness of his character; and of his oratorical powers it is enough to record, that Burke called him 'the greatest debater the world ever saw,' and Sir James Mackintosh, 'the most Demosthenian speaker since Demosthenes.' His remains were inter-

red in Westminster Abbey, near to those of Pitt. See, besides the *Life and Times* and the *Memorials and Correspondence*, by Earl (then Lord John) Russell, the *Character of the Late C. J. Fox*, by Dr. Parr (1809), and the interesting *Early History of C. J. Fox*, by G. O. Trevelyan (1880).

FOX, GEORGE, the originator of the Society of Friends (q. v.), commonly called Quakers, was born at Drayton, in Leicestershire, in 1624, and at an early age was employed in keeping sheep. Subsequently, he was apprenticed to a country shoemaker, but when about 19 years of age, his religious impressions produced such a strong conviction in him, that he believed himself to be a subject of a special Divine call; and abandoning his universal avocations, wandered solitarily through the country, dressed merely in a leathern doublet of his own making, and absorbed in spiritual reveries. After some time, his friends induced him to return home, but F. stayed with them only for a short period, and finally adopted the career of an itinerant religious reformer. About 1646, he left off attending church for divine worship, but did not scruple to interrupt the services when conducted by 'professors,' i. e. formalists, or persons whom he believed not to be genuine Christians. His first efforts at proselytism were made at Manchester in 1648. The excitement caused was very great, and, in consequence, F. was imprisoned for some time as a disturber of the peace. It may be proper to mention here, that the leading doctrines or convictions were the futility of learning for the work of the ministry, the presence of Christ in the heart as the 'inner light,' superseding all other lights, and the necessity of trying men's opinions and religions by the Holy Spirit, and not by the Scriptures. F. next traveled through various of the midland counties, Derby, Leicester, and Northampton, exhorting the people in public places to forsake all vicious practices, drunkenness, swearing, &c., and to cultivate the Christian graces. He had a winning manner and by his extreme earnestness made many converts. His followers were first contemptuously called 'Quakers' in 1650.

According to Fox's own account, given in his *Journal*, 'This was Justice Bennet of Derby, who was the first that called us Quakers, because I bade them tremble at the word of the Lord.' The name has been commonly explained from the Quakers' agitation when 'moved by the Holy Ghost.' In 1655, F. was brought to London, and examined before Cromwell, who quickly saw that there was nothing in Quakerism to excite his apprehensions, and pronounced the doctrines and the character of its founder to be irreproachable. Nevertheless, for some years after this, F. had a hard struggle with his Puritan antagonists. In an age of dogmatism and fanaticism, it was not to be expected that the half-mystical spiritualities and grotesque practical crotchets of the Leicestershire shoemaker could meet with any official toleration. F. was constantly vilified and frequently imprisoned by country magistrates. In 1669, he married the widow of Judge Fell. He then went to America, where he spent two years in propagating his views with much success. On his return to England in 1673, he was imprisoned for some time in Worcester jail, under the charge of having 'held a meeting from all parts of the nation for terrifying the king's subjects.' On his release, he visited Holland, and afterwards Hamburg, Holstein, and Danzig, always endeavoring to persuade men to listen to the voice of Christ within them. He died in London, January 13, 1691. F. was not a man of broad and philosophic genius; he did not enrich the world with the multitude of his thoughts; in fact, there is a conspicuous poverty of intellect and sentiment manifested in his writings, but (as often happens in the case of a mystic) the earnestness and clearness with which, in the opinion of many, one great truth of Christianity was realized, imparted a power and efficacy to his words that genius itself might envy. His doctrine of the universal 'inner light'—defended in a more learned fashion by Barclay (q. v.) in his *Apology for the Quakers*—may be regarded as a protest against the narrow or at least excessive 'scripturalism' of his age, but his understanding was not sufficiently clear and strong to guide him safely in all the consequences which he ventured to deduce from it. Hence have sprung most of the *miseries* of Quakerism. His writings were collected and published in 3 vols., 1694—1706. An edition in 8 vols. has been published at Philadelphia, United States.—Compare Sewel's *History of the Quakers*; Neal's *Puritans*; Marsh's *Life of Fox* (1848); and *Lives* by Janney (Phila. 1853), Watson (Lond. 1869), &c.

FOX, WILLIAM JOHNSON, orator and political writer, the son of a small Suffolk farmer, who afterwards settled as a weaver at Norwich, was born in 1786. He gave early promise of talent, and was sent to Homerton College, to be trained for the ministry of the Independents. He subsequently seceded to Unitarianism, but ultimately shaking off all allegiance to existing Christian churches, he delivered a series of prelections at his chapel in South Place, Finsbury, which marked him out as the leader and organ of English rationalism.

When the Anti-corn-law League enlisted the ablest platform orators of the day in the service of free trade, his bold and impassioned rhetoric greatly contributed to arouse and intensify public feeling. M. Guizot quotes his speeches as the most finished examples of oratory which the great conflict produced. Their effect upon the vast metropolitan audiences to which they were addressed was electric. F. also contributed by his pen to the success of free trade, and his *Letters of a Norwich Weaver Boy* were largely quoted and read. After the abolition of the Corn Laws, he was invited to stand for Oldham, which borough he continued to represent till 1863 since 1847. Like most men who enter the House of Commons late in life, F. did not altogether realize the oratorical promise of his platform and pulpit career. His best parliamentary speeches were upon the education of the people. As a politician he was ever a consistent member of the advanced Liberal party. A succession of illness in his late years interfered with his attendance in parliament. He was among the earliest contributors to the *Westminster Review*, edited for many years the *Monthly Repository*, and largely contributed to various other organs of public opinion. His *Lectures, chiefly addressed to the Working-Classes*, were published in 3 vols. He is the author of a philosophical dissertation on *Religious Ideas*, and other theological works. He died in 1864.

FOX (*Vulpes*), a genus of *Canidae* (q. v.), particularly distinguished from dogs, wolves, jackals, &c., by the pupils of the eyes contracting vertically, and in the form of the section of a lens, not circularly. This takes place whenever the eyes are turned to a strong light, and foxes are all nocturnal animals. Foxes are also generally of lower stature in proportion to their length than the other *Canidae*; they have a roundish head, with a very pointed muzzle, short triangular ears, slender limbs, and a bushy tail

The Common Fox (*Vulpes vulgaris*).

They dig burrows for themselves in the earth, or take possession of holes already existing. They are famous for their cunning, which they exhibit both in their artifices for obtaining prey, and for escaping from danger. They feed on small quadrupeds, birds, eggs, &c.; some of them, however, also partly on fruits and other vegetable substances.—The COMMON FOX (*V. vulgaris*), a native of most parts of Europe, is the only British species, and is still pretty abundant in most parts of the country, although from many parts it would probably have been extirpated ere now, unless it had been in some measure protected with a view to the sport of fox-hunting. The common fox is reddish brown above, white beneath; the outside of the ears black, a black line extending from the inner angle of the eye to the mouth; the legs mostly black, the end of the tail generally white, although specimens sometimes occur in which it is gray, or even black. There are at least three varieties known in Britain, pretty well marked by difference of size and form—the *Greyhound Fox* being more slender and longer-limbed, and the *Cur Fox*—frequent in upland moorish districts—being smaller than the common variety. Other varieties occur in the north of Europe.

The Fox has a gland under the tail, which secretes a very fetid substance, communicating to the whole animal its well-known smell. It breeds once in a year, having usually four, five or six young ones in a litter. Its usual voice is a kind of yelp. Its senses of sight, hearing, and smelling are very acute. Innumerable anecdotes are on record illustrative of its cunning. The difficulty of setting traps so that they shall not be detected and avoided by it, is well known. Foxes are said to have been observed approaching water-fowl by swimming slowly with a turf in the mouth, so as to remain concealed. A most trustworthy person assured the writer of this article, that he saw a fox approach a group of hares that were feeding in a field, with a slow, limping motion, and having his head down as if eating clover, till he was near enough, by a sudden rush, to secure very different food. Foxes captured in hen-roosts have often been known to simulate death, and to submit to being dragged about and very roughly treated without a sign of life, till an opportunity of es-

cape presented itself. When they are driven to their holes, and these are surrounded with traps, they not unfrequently show such a just appreciation of the danger, that they will endure starvation for days and even weeks rather than come out. Even when taken young, the common fox can hardly be tamed; and very few instances are on record of its showing even a little of that attachment to man of which so many animals are capable, and for which the dog is so remarkable. The improbability of any of the domestic races of dog being at all derived from the fox, is noticed in the article DOG. The French *renard* appears in English in *reynard*, the familiar appellation of the fox. The south of Europe produces foxes of smaller size than the common fox, having the fur of the belly black, regarded by some as a mere variety by others as a distinct species (*V. melanogaster*). They are less carnivorous, and to them some of the allusions and fables relate—as of the fox and grapes, &c.—which do not accord well with the habits of the foxes of Britain and of Northern Europe.—The Himalaya mountains produce a species of fox (*V. himalaicus*) very similar to the common fox, but of superior size and brilliancy of colors. The fur is rich and fine.—The BLACK FOX of Northern Asia is also very similar to the common fox, but is entirely of a velvety black color, except the tip of the tail, which is white; its fur is greatly esteemed, brings a high price, and forms an article of export from Kamchatka to China.—The COAL FOX (*V. alopec*) of some parts of Europe, as Switzerland and Bavaria, is by some naturalists regarded as distinct from the common fox. It is of inferior size, more timid, and less troublesome; the tip of the tail is black.—North America has several species of fox of which the RED FOX (*V. fulvus*) very nearly resembles the common fox of Europe, but is of rather larger size, has a shorter muzzle, eyes nearer each other, and a more copiously bushy tail. Its fur is also longer, finer, more brilliantly covered, and much more valuable, forming a considerable article of export from fur countries; in which, as well as in Canada, and in the northern parts of the United States, this species is abundant. The CROSS FOX is a variety of it, distinguished by a longitudinal dark band along the back, crossed by a transverse band over the shoulders. The burrow of this fox 'at first inclines downwards for four or five feet at an angle of about twenty-five degrees, it then inclines upwards a little, which is a security against inundations, and is continued at a depth of about three or four feet from the surface, until it reaches a point where it is divided into two or three galleries.'

Great numbers of these foxes are annually tracked to their burrows, and digged or smoked out of them by American farmers.—The GRAY FOX (*V. virginianus*) is the most abundant species of the southern states, extending, however, as far north as Canada, where it is rare. It is of a gray color, varied with black, is about the size of the common fox, but not so bold, and sometimes eats vegetable substances, such as ears of maize. The gray fox exhibits not a little of that cunning for which the common fox is celebrated, and when pursued by hunters and hounds, has been known to escape by getting upon the rail of a fence and running along it for some distance, so that the scent was lost. This was on one occasion done on the newly-laid rail of a railroad elevated above a swamp. It is not unfrequent for the gray fox, when hard pressed, to take refuge in a tree, particularly if one which has somewhat fallen from the perpendicular presents itself.—There are a number of other species of fox, Asiatic, African, and American; but the most deserving of notice is the ARCTIC FOX (*V. lagopus*), which inhabits the most northern parts of Europe, Asia, and America. It is very plentiful in Iceland, feeding much on ptarmigans, and sometimes on young lambs. Great numbers are found on the shores of Hudson's Bay, particularly during winter, and they have been supposed to migrate thither from still more northern regions; but it has been ascertained that this animal spends the winter even in the most northern regions that have ever been visited by man, braving the cold of Melville Island and Banks's Land, finding abundant food in the hares, marmots, ptarmigans, and other animals which also remain there. The Arctic Fox is rather smaller than the common fox; it is more densely clothed with a woolly fur, which on some parts is two inches in length; the tail is extremely bushy; and even the soles of the feet are thickly covered with hair. The color is pure white in winter, at least in very cold climates; varying to a brownish or bluish color in summer. It is gregarious, and many burrows are often found together. It is extremely cleanly in its habits, and is quite devoid of the offensive smell which belongs to most of the foxes; it is also much less cunning, and much more easily trapped, as well as much more gentle and capable of being tamed. Its flesh has been sometimes eaten by arctic voyagers, with a relish due to the extreme cold of the climate, and the consequent demand of the system for animal food. Its fur is not nearly equal in value to that of the red fox.

FOXES, JOHN, the martyrologist, was born of respectable parents in 1517, at Boston, Lincolnshire. In 1533, he entered as a student at Brasenose College, Oxford; in 1538, he took his

Bachelor's, and in 1543, his Master's degree, and was elected a fellow of Magdalen College. He displayed at an early period an inclination for Latin poetry, and wrote several plays in that language upon scriptural subjects. Of these, the only one that remains, entitled *De Christo Triumphante*, was printed at London in 1551, and at Basel in 1556, 8vo., and 1672.

The religious movements of the times led him to study the great controversy between Popery and Protestantism, and becoming a convert to the principles of the Reformation, he was, July 22, 1545, expelled from his college for heresy. His father being dead, and his mother married again, his stepfather refused him any further aid, and he was, in consequence, reduced to great distress. For a short time, he was employed as tutor to the children of Sir Thomas Lucy of Charlecote, Warwickshire, and afterwards was engaged by the Duchess of Richmond as tutor to the children of her brother, the Earl of Surrey, then a state prisoner in the Tower. In this capacity he remained during the whole reign of Edward VI., but was never, notwithstanding Anthony Wood's assertion to the contrary, restored to his fellowship at Magdalen. On June 23, 1550, he was ordained deacon by Ridley, Bishop of London, and preached the doctrines of the Reformation at Reigate. During the reign of Mary, he retired to the continent. On the accession of Queen Elizabeth, he returned to England in October 1559; and in May 1563, he was inducted into the canonry and prebend of Shipton, in the cathedral of Salisbury. He also enjoyed the living of Cripplegate, which he soon resigned, and for a year he held a stall at Durham. In 1575, when some Dutch Anabaptists were condemned to the flames in London, F. interceded for them with Queen Elizabeth and other persons in authority, but without effect. He wrote numerous controversial and other works, but the one that has immortalized his name is his *History of the Acts and Monuments of the Church*, popularly known as *Foxe's Book of Martyrs*, the first part of which was published at Strasburg in 1554. The first English edition appeared in 1563, in one vol. folio. Sanctioned by the bishops, it was ordered, by a canon of the Anglican Convocation, to be placed in the hall of every episcopal palace in England, and has gone through innumerable editions. It is not a very critical work, as might naturally be supposed, and Roman Catholics deny its trustworthiness. F. died in 1587, in his 70th year, and was buried in the chancel of St. Giles, Cripplegate, London.

FOXES AND FOX-HUNTING. The law with reference to fox-hunting, which is a matter of a good deal of importance in many parts of the country, seems to stand thus in England: 'Though in general all persons who go upon another's lands without permission are trespassers in the eye of the law, yet there are some cases where the trespass is said to be justifiable,' says Mr. Paterson, the most recent writer on the subject, and he quotes Blackstone's dictum to the effect that 'the common law warrants the hunting of ravenous beasts of prey, as badgers and foxes, in another man's land, because the destroying such creatures is said to be profitable to the public' (3 Black. Com. 212). Care must be taken, however, that no damage be done beyond what is necessary for the public good, for that is the ground on which alone the legal character of fox-hunting can be maintained. It was found, moreover, in the *Earl of Essex v. Capel* (1 Chitt. Game L. 114), that though pursuing a fox on another's land be justifiable, yet, if it take to earth, or to a house there, it is not justifiable to dig or break doors for it.

In Scotland, where, from the character of the country, fox-hunting is often impossible, it never has become a national sport to the same extent as in England; and consequently, the rule that one is entitled to enter on the lands of another for the purpose of killing a fox, has been confined to those cases in which he is pursued simply as a noxious beast, and fox-hunting for sport without leave has been held to be punishable as a trespass, and the trespasser held liable for whatever surface-damage he may occasion. In Ireland (by 1 and 2 Will. IV. c. 32, s. 35), persons pursuing with bounds any fox, hare, or deer which has been started elsewhere on another's land, are exempted from summary proceedings for trespass.

FOXGLOVE. See DIGITALIS.

FOXHOUND, a kind of dog much used in Britain for the sport of fox-hunting. It is not quite so large as the staghound, and is perhaps a mixed breed between the staghound or the bloodhound and the greyhound. The color is commonly white, with large patches of black and tan color. Their speed and perseverance are remarkable; they have been known 'to run hard for ten hours before they came up with and killed the fox, and the sportsmen were either thrown out, or changed horses three times.'

FOX-HUNTING, from its exciting nature, as well as from the qualities of daring courage and cool calculation requisite in those who thoroughly follow and appreciate it, has long been termed the king of British national sports.

In Great Britain, there are upwards of 100 hunting establishments, of which by far the greater proportion belong to the

counties south of the Tweed. Fox-hunting establishments—which are in most instances supported by subscription, though sometimes owned by private gentlemen of wealth and influence—are organized and maintained at a very considerable annual cost, the price of a single pack of foxhounds sometimes amounting to several thousand guineas. Every establishment is under the direct superintendence and control of one experienced gentleman, the *master*, and under him again rank the huntsman, whippers-in, earth-stopper, kennel-servants, &c. A 'pack' is composed of from 20 to 60 couples of hounds, the number greatly depending upon the frequency of hunting-days: thus, some packs hunt six days, some five days, others four, and many only two days a week; 30 couple of hounds is a good average; these are carefully reared, fed, and otherwise attended to. The master himself, as a matter of course, has the general superintendence of the servants, hounds, and horses; and in the hunting-field is general director of the proceedings. Next to him come the huntsman and one, or two 'whippers-in' ('whips'). The huntsman, who is practically the most important personage in the field, requires to see that his hounds are properly managed and fed in their kennels; duly led to the place of meeting on hunting-days; and, what is of more consequence still, that they receive fair-play in the field, and find and hunt their foxes in true style.

The huntsman requires to be a man of great nerve and much activity: he should also have a good head, a clear ringing voice, a keen eye, and above all he must be a first-rate horseman, and know thoroughly every point in the country over which he hunts. He has often to restrain heedless riders, and 'keep the field back'; a duty requiring firmness of character, with a quiet and civil manner. With these necessary qualifications, and having so many responsible duties on his shoulders, he is treated with great respect by those for whom he provides sport: he is mounted on the best horses his master can produce, and may be said to conduct and direct the hunt from the moment the fox is found till the moment of his death—from 'find to finish.'

The duties of the first whipper-in, though not so responsible as those of the huntsman, are still considerable: for instance, he takes a certain management of the hounds in kennel, assists in conducting the hounds to the 'meet,' and aids the huntsman in various ways during the run. His knowledge of the management of hounds, and of fox-hunting generally, must at the same time be such as to enable him to occupy the huntsman's place in an emergency. The 'second whip's' principal duty is that of bringing up and urging on lagging hounds in the field, by lashing and 'rating.' In many hunts, however, a second whipper-in is dispensed with.

A considerable range of country is necessary for the full enjoyment of fox-hunting, the best being that which is diversified by pasturage and plantation. Being a nocturnal feeder, the fox quits his burrow or 'earth'—which is generally in a gorse brake, or a plantation or covert of underwood—during the night, and returns to it in the morning, and this fact is taken advantage of by those who hunt him for sport. The day and place of 'the meet' are duly advertised, and on the night before the hunt, the coverts to be 'drawn' next day are visited either by a duly appointed *earth-stopper* or by the gamekeeper, who, knowing that the foxes are from home, proceeds, spade in hand, from one hole to another, filling them up with earth and brushwood as he goes. Thus, the fox, upon returning at dawn to his 'earth,' finds ingress denied, and so betakes himself to some neighboring thicket, or to some unenclosed cover of gorse, rushes, &c., where he makes a temporary lair or 'kennel.' When the earths have been carefully closed, the earth-stopper returns home and informs the huntsman, or first 'whip,' as to their number and locality, and that information forms a guide for the proceedings of the following day. (After hunt is over, the earths are reopened, and as little trace as possible left of the work.) The hour of 'the meet' is usually ten or eleven o'clock A.M., and at the appointed place assemble the whole field, including master, huntsman, whippers-in, hounds, and those gentlemen (and frequently ladies) who intend either to participate in the day's sport, or merely to see the 'hounds throw off.'

When a covert is reached, the huntsman, by a wave of his hand, or a few familiar words, such as 'Eu in! eu in there! good dogs!' 'throws in' his hounds, following immediately after with the first 'whip.' The mounted gentlemen usually remain outside, and take their directions as to stance, &c., from the master, who from this time forward does his best to control and direct their movements. In fact, the master may be said to have the control of the 'field'—that is, the riders—and the huntsman that of the hounds and hunt. The second whip being posted at the covert side, near where it is expected a fox may burst through or 'break,' one or two of the more eager riders are sometimes permitted to jump their horses into the covert, if it be large, to assist in the finding of the fox. Those who remain outside then prepare themselves for their work, and eagerly listen for the first token of the presence of reynard; this is betrayed by a slight but

anxious whimper or whine from the 'challenging' hound—that is, the hound (usually an old and experienced one) that first perceives or 'hits' the scent of a fox—and is soon followed by others, who instantly rush to his side. The huntsman, if he be tolerably certain that the game scented is no other than a fox, at judicious intervals urges on his hounds by familiar expressions, such as 'Yoicks, yoicks, have at him!' 'Push him up!' &c., till the fox is fairly roused from his kennel, and steals away. It sometimes happens, while 'drawing' coverts, that hounds will come suddenly upon a fox, and seize him before he has time to escape. This is termed 'chopping,' and is always to be prevented if possible. If the covert be very thick, a fox may leave his kennel unperceived; and when he does so, he usually runs through or round the covert for a considerable distance before quitting it for the open fields. He may also 'run his foil,' by doubling back and forward on the same path or track, and thus possibly baffle the hounds, even when they 'own his scent.' In large coverts, too, a fox frequently 'hangs'; that is, he remains in it for a long time before going away. The person who first sees the fox 'break cover,' or, in other words, 'views him away,' should always allow him a certain 'law' before giving the 'view halloo,' as a fox will frequently turn or 'head back' into the covert if he hears any unusual noise at the instant of his quitting it. When, however, the person or persons who are watching see that the fox is really off, notice is instantly given to those within the thicket, and those without, by the cry of 'Hou—y! hou—y! Tallyho! Gone away! GONE A-WAY!!' upon which the huntsman blows his horn to collect his hounds; the whipper-in drives out lagging members of the pack, either with his whip or by some cry; the master restrains the more impatient of the riders till the huntsman and hounds have 'settled to' their fox; and then he and the entire field join in the chase, and the first, and frequently the most exciting, part of the day's proceedings has commenced—the fox has 'broke cover,' the hounds have been 'laid on,' and the field has entered on its impetuous 'first burst.'

A certain etiquette is, however, absolutely necessary in allowing the hounds and huntsman to get away *first*; but after that, each rider, with a certain deference to the master, chooses his own place in the hunt, and does his best, independently of his neighbors, to keep at a certain distance, not directly in the line, but to one side and in the rear of the hounds. When a rider happens to

Fox-hunting—'Laying on' the hounds.

be near the pack at the first burst, and gets a good position in following them, he is said to 'get well away with the hounds,' and if well mounted and a skilful rider, his chances of both viewing the hunt and being 'in at the death' are very considerable. And now, as we have already said, begins the grand excitement of the day; the fox being fresh, races away at tremendous speed, followed by perhaps upwards of twenty couple of hounds at full cry. If the day is propitious (a 'southerly wind and cloudy sky' having long retained favor), the scent of the retreating fox lies well, especially at first, when it is called 'burning' or 'breast-high,' and is for many minutes 'owned' by at least all the leading hounds in the pack, though, perhaps, the object of pursuit itself is far ahead, and out of sight; and away streams the hunt over hedges, ditches, and gates, across rivers, railways, arable land, and grass pastures, perhaps for several miles before a single *check* occurs. Now, the foxhound hunts almost entirely by scent, and does not, like the greyhound, depend upon the eye. The fact of scent failing, therefore, at any time during the hunt, throws out the hounds, and prevents them from renewing it, until the scent is recovered, or 'hit off.' When the scent is 'burning,'

hounds run almost mute, though at first, and at intervals afterwards, they usually 'throw their tongues' pretty freely. When all the hounds are giving tongue, they are said to be at 'full cry,' and 'carry a good head,' the scent being on such occasions so thoroughly diffused as to be felt or 'owned' breast high by probably every member of the pack. Sometimes scent becomes so faint as to be hardly perceptible, and when this is the case, the energy of the hounds abates considerably; they then run with their heads close to the ground, and are said to hunt a 'cold' scent. Here, however, a little timely assistance from the huntsman is of the greatest moment in restoring animation to the pack. He waves his cap, blows his horn, and encourages his hounds by well-known expressions, to renewed exertions.

When, as frequently happens from various causes, the scent fails entirely—such as the fox crossing water, running through a drove of sheep, 'heading back' in another direction, running along or lying upon the tops of walls or thick hedges, &c.—the hounds cease 'giving tongue,' suddenly stop, throw up their heads, and are 'at fault.' In this emergency, the 'field' remains at a respectful distance behind, and the huntsman knowing, or at least guessing by experience which way the fox has taken, or the special means he has adopted for foiling the scent, allows his hounds at first, for a few moments, themselves to attempt to regain it; but failing that, and finding that his interference and assistance are necessary, he instantly blows his horn, and calls or 'lifts his hounds' from the place, and 'takes a cast' round and round about the spot where the scent failed, cheering them on the while. Thus, by gradually widening his casts, the scent is very frequently recovered or 'hit off,' a circumstance which is soon made apparent by the whimper of recognition given by the hound that first 'owns it,' followed by the answering tongues of the whole pack. When the hounds, however, fail to 'hit off' the scent, if the day be far advanced, they are taken home, or they are trotted on to some neighboring covert, which is drawn for a fresh fox.

When the fox is killed, either in 'the open' or elsewhere, the rider who is first in at 'the death'—usually the huntsman—springs

The midland counties of England, such as Leicester, Northampton, Warwick, Yorkshire, &c., are the best for hunting purposes in Great Britain; and owe their superiority in a great measure to two causes: 1st, the strict preservation and consequent number of foxes; and 2d, the extensive tracts of pasturage being favorable both for running and scent. The instinct of the fox leads him, as a general rule, to run *down* wind, that his scent may not be blown to the hounds; he also takes advantage of every peculiarity in a country likely to offer him an advantage over his foes.

The fox-hunter must be possessed of considerable courage, united with coolness, and must be a judge of pace and have a good eye in 'riding to hounds,' to avoid tiring or 'overmarking' his horse unnecessarily. Much of the excitement and pleasure of the fox-hunter consists in his successfully leaping the various hedges, ditches, fences, &c., encountered; but at the same time, a really skilful and humane rider, however well mounted, will never knowingly urge his horse at a fence or leap of any kind, unless he is positively certain it is within his horse's power; and if he finds his horse betrays symptoms of distress, he will rather turn his head homewards, and forego the chase, than overtax its courage and strength.

Much useful and entertaining information on fox-hunting occurs in Blaine's *Encyclopædia of Rural Sports* (London, Longmans); *British Rural Sports*, by Stonehenge; Beckford's *Thoughts on Hunting*; *Reminiscences of a Huntsman*; *Nimrod*; *The Field* newspaper; &c.

Fox-hunting is not practised after the English fashion in the northern states of America, but in the southern states from Maryland to Florida, it is a favorite amusement. The object of pursuit, however, is the *Gray Fox* (*Vulpes Virginianus*), and the chase is not so severe, and seldom lasts so long as that of the common fox.

FOX ISLANDS, another name for the ALEUTIAN ISLANDS (q. v.).

FOX RIVER is the name of two considerable streams in the United States of America, both of them rising in Wisconsin.—1. The F. R., or *Pishtaka*, is an affluent of the Illinois, which is itself a tributary of the Mississippi. It is 200 miles long, and is valuable chiefly for its water-power.—2. The F. R., or *Neenah*, after a course of about the same length, falls into Green Bay in Lake Michigan. It is divided into two sections by Lake Winnebago, the upper one being connected by a canal with the Wisconsin, so as to link together the Mississippi and the Great Lakes of the St. Lawrence.

FOX SHARK, or THRESHER (*Alopias* or *Alopecias*), a genus of sharks, containing only one known species (*A. vulpes*), an inhabitant of the Mediterranean and of the Atlantic, and occasionally seen on the British coasts. The snout is short and conical; the spout-holes are very small; the mouth is not so large as that of the white shark, nor the teeth so formidable; but the F. S. is extremely bold and voracious, readily attacking grampuses or dolphins much larger than itself. Its most remarkable peculiarity is the great elongation of the upper lobe of the tail-fin, which is nearly equal in length to the whole body, and into which the vertebral column extends. Of this it makes use as a weapon, striking with great force. It is said to be not uncommon for a whole herd of dolphins to take flight at the first splash of the tail of a fox shark. From the use which it makes of its tail, it has acquired the name of Thresher. It attains a length, tail included, of 13 feet. The body is spindle-shaped.

FOXTAIL GRASS (*Alopecurus*), a genus of Grasses, distinguished by a spiked panicle, two glumes nearly equal, and generally united at the base, enclosing a single floret which has a single palea, with an awn rising from the base. The species are chiefly natives of temperate countries, and about six are British. MEADOW FOXTAIL GRASS (*A. pratensis*), which has an erect smooth culm about 1½–2 feet high, and a cylindrical obtuse panicle abundantly covered with silvery hairs, is one of the best meadow and pasture grasses of Britain, but does not arrive at full perfection till the third year after it is sown. It bears mowing well, and is reckoned a good grass for lawns. It bears drought well. The JOINTED FOXTAIL GRASS (*A. geniculatus*), with an ascending culm bent at the joints, is very common in moist places, and cattle are fond of it, but it is a small grass. The SLENDER

Blood Hunter clearing a stone wall in good style (from Blaine's *Encyclopædia of Rural Sports*).

off his horse, with a 'Who! whoop!' lashes the hounds off, and cuts off the head, feet (*pads*), and tail (the *brush*). He then flings the carcass to the hounds, who tear it to pieces, and devour it in a very few minutes. The brush is usually presented to any lady who may happen to be in at the death, or is claimed as a trophy by one or other of the gentlemen present. The *pads* likewise are distributed amongst those who may wish to preserve mementos of the chase. As a general rule, the huntsman, and several of the best mounted in the field, manage to be in, either at or immediately after the death, though instances are not wanting when, during unusually protracted runs, the hounds have left every rider far behind, and have followed and killed their fox miles away from the spot where the last horseman had given in. A strong fox will frequently 'live' before hounds for an hour or an hour and a half; but cases have been known when this has been far exceeded, and when the run has extended to thirty or even forty miles, and has lasted all day, and even into the night. Young foxhounds begin their career by what is termed *cub-hunting*; but this, however necessary it may be for teaching them, is considered inferior sport to regular hunting.

Foxtail Grass (*Alopecurus pratensis*):
a, glume; b, floret.

FOXTAIL GRASS (*A. agrestis*) is an annual or biennial, of little value except for light sandy soils, on which it is sometimes sown. A foreign species (*A. nigricans*), a native of the continent of Europe and of Siberia, has been introduced into Britain, and appears likely to prove valuable. It has somewhat creeping roots, is a little larger and stronger than *A. pratensis*, and is rather earlier.

FOY, MAXIMILIEN SEBASTIEN, a distinguished French general and orator, was born at Ham, 3d February 1775. In 1791, he was one of the volunteers who hastened to defend the frontiers of their country against foreign invasion, and during the next nine years served with distinction under Dumouriez, Moreau, and Massena. In 1800, he was raised to the rank of adjutant-general in the division of Moncey, in the army of the Rhine, which marched through Switzerland into Italy, where he commanded the vanguard of the army in 1801. In 1805, he commanded the artillery of the second division in the Austrian campaign. In 1807, Napoleon sent him to Turkey at the head of 1200 artillerymen, to assist Sultan Selim against the Russians and British. After the revolution in which Selim was dethroned, F., under the direction of the French ambassador, General Sebastiani, defended Constantinople and the Strait of Dardanelles so effectively, that Duckworth, the British admiral, was obliged to retire with loss. From 1808 to 1812, F. was general of division of the army in Portugal. His talents were exhibited to advantage in conducting the retreat of the French army across the Douro. F. was present at all the battles of the Pyrenees, and at Orthez, in 1814, was dangerously wounded. In the campaign of 1815, he commanded a division on the field of Waterloo, where he was wounded for the fifteenth time. In 1819, he was elected deputy by the department of Aisne. In the chamber, he was the constant advocate of constitutional liberty, and showed great rhetorical talent and knowledge of political economy. He distinguished himself particularly by his eloquence in opposing the war against Spain in 1823. F. died at Paris, November 28, 1825. Madame Foy published, in 1827, from her husband's papers, a *Histoire de la Guerre de la Péninsule*. In the previous year appeared his *Discours*, with a biography.

FOY'ERS, a stream rising in the Monadleadh Mountains, in the middle of Inverness-shire. It runs 12 miles north, and falls into the east side of Loch Ness, nearly opposite Mealfourvounie Mountain. It has two celebrated falls within a mile and a half of its mouth, where the stream rushes through a deep, narrow ravine in the hills, skirting the east side of the loch. The upper fall is 30 feet high. The stream then descends 30 feet in a quarter of a mile. The lower fall (specially called *The Fall of Foyers*), is 90 feet high. It is one of the finest cascades in Britain.

FOYLE, LOUGH, an inlet of the Atlantic, on the north coast of Ireland, between the counties of Derry and Donegal. It is triangular in form, 16 miles long from north-east to south-west, 1 mile wide at its entrance, and 9 miles broad along its south side. A great part is dry at low water, and its west side alone is navigable. Vessels of 600 tons ascend the west side of the lough, and its chief tributary the Foyle (which comes 16 miles from the south), to Londonderry. On the east shore is a flat strand with a sandy beach, on which, in 1827, was measured a line of 41,640, which was afterwards extended by triangulation to about 53,200 feet, and formed the base line of the Ordnance Survey of Ireland.

FRA BARTOLOMEO. See BACCIO DELLA PORTA.

FRACASTORO, GIROLAMO, an Italian savant and philosopher, famous for the universality of his learning, was born of an ancient family at Verona in 1483. At the age of 19, he was appointed professor of logic in the university of Padua. But his knowledge embraced the most divergent sciences, and on account of the eminence in the practice of medicine, he was elected physician of the Council of Trent. His Latin verse also exhibits remarkable elegance. He died in 1553. A bronze statue was erected in his honor by the citizens of Padua, while his native city commemorated their great compatriot by a marble statue. His writings in prose and verse are numerous. The chief are—*Syphilis sive Morbi Gallici* (Verona, 1530, in 4to; Paris, 1531 and 1539, in 8vo; London, 1729, in 4to, and 1746, in 8vo; Italian edition, Verona, 1739, in 4to, by Tiraboschi; Naples, 1731, by Pietro Belli); *De Vini Temperatura* (Venice 1534, in 4to); *Homocentricorum sive de Stellis, De Causis Criticorum Dierum Libellus* (Venice, 1535, in 4to); *De Sympathia et Antipathia Rerum De Contagionibus et Contagiosis Morbis et eorum Curatione* (Venice, 1546, in 4to; Lyon, 1550, 1554, in 8vo). The collective works of F. appeared for the first time, Venice, 1555, in 4to.

FRA'CTED, heraldically, signifies broken asunder.

FRACTION. In Arithmetic, a fraction is any part or parts of a unit or whole, and it consists of 2 members, a denominator and a numerator, whereof the former shows into how many parts the unit is divided, and the latter shows how many of them are taken in a given case. Thus $\frac{3}{4}$ denotes that the unit is divided into four parts, and that three of them are taken; and more generally $\frac{a}{b}$ denotes that the unit is divided into b parts, and that a of

them are taken. A fraction is called *proper* when the numerator is less than the denominator, and *improper* when the numerator is greater than the denominator. In Algebra, any quantity $\frac{a}{b}$ is called a fraction, although a and b are not necessarily representatives of whole numbers, as they would require to be if the fraction be an arithmetical fraction. The algebraical fraction $\frac{a}{b}$ just means that any quantity affected by it is to be multiplied by a , and divided by b . This definition, however, through the greater generality of algebra, includes that of an arithmetical fraction. The rules for the addition and multiplication of fractions are the same in algebra and arithmetic. To add two or more fractions together, we must bring them to a common denominator, and add the numerators for a new numerator, and take the common denominator for the new denominator. Thus if $\frac{a}{b}$, $\frac{c}{d}$ be two frac-

tions, then $\frac{a}{b} + \frac{c}{d} = \frac{ad}{bd} + \frac{cb}{bd} = \frac{ad+bc}{bd}$, the fractions being brought to a common denominator by (as a general rule) multiplying each numerator by every denominator, except its own, and multiplying all the denominators for the common denominator.

To subtract two fractions, we bring them to a common denominator, and subtract their numerators for the new numerator. Thus $\frac{a}{b} - \frac{c}{d} = \frac{ad-bc}{bd}$. To multiply two fractions together, the rule is, to multiply the numerators together for a new numerator, and the denominators together for the new denominator. Thus $\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$. The reasons for all these rules are obvious. The rule of division is to invert the divisor, and proceed as in multiplication. This follows from the consideration, that to divide is the inverse of to multiply, and that to divide by $\frac{a}{b}$ must be the same thing as to multiply by $\frac{b}{a}$.

FRACTIONS, CONTINUED. If $\frac{A}{B} = a + \frac{a_1}{B}$, and $\frac{B}{a_1} = b + \frac{b_1}{a_1}$, and $\frac{a_1}{b_1} = c + \frac{c_1}{b_1}$, and... $\frac{k_1}{l_1} = m + \frac{m_1}{l_1}$, and $\frac{l_1}{m_1} = n + \frac{n_1}{m_1}$, &c.

$$\text{Then } \frac{A}{B} = a + \frac{1}{\frac{b}{c} + \frac{1}{\frac{d}{\dots} + \frac{1}{\frac{m}{n} + \dots}}}$$

This expression for the value of $\frac{A}{B}$ is called a continued fraction.

If we consider the fractions (1) $\frac{a}{1}$, (2) $a + \frac{1}{b}$ or $\frac{ab+1}{b}$, (3), $a + \frac{1}{b + \frac{1}{c}}$ or $\frac{(ab+1)c+a}{bc+1}$ formed by taking into account parts only of the denominator in the continued fraction, we obtain a series of fractions converging to the value of $\frac{A}{B}$. These converging fractions are always approximating to the value of $\frac{A}{B}$, and are alternately greater and less than it. Throughout the series, the 1st, 3d, 5th, 7th, &c., are each below the true value, while the 2d, 4th, &c., are above it; or *vice versa*, according as the original fraction is improper or proper. It can be shown that the successive converging fractions approach nearer and nearer to the true value of the continued fraction. Converging fractions are of great use in the summation of infinite series.

the queen of Naples and the British admiral, Sidney Smith, whose influence had not sufficed to rescue him from death, although on his capture he produced papers bearing the royal seal, which vouched for his right to the rank of colonel in the royal forces.

FRAGA, a town of Spain, in the province of Saragossa, 63 miles west by south from Saragossa, on the left bank of the Cinca, which is crossed by a suspension bridge. The town stands on a slope, and is poor and half-ruinous, with ill-paved streets. The environs abound in pomegranates and figs. The small green figs of this district are celebrated as particularly delicious, and when dried form the chief article of export. F. is supposed to occupy the site of the ancient *Gallica Flavia*. Pop. 5028.

FRAGA'RIA. See **STRAWBERRY**.

FRAME, in Gardening, the covering of any kind of hotbed, flued pit, or cold pit, used for the cultivation of plants not sufficiently hardy for the open air. Frames are of various materials, but generally of wood or iron and glass, and are made in one piece or in sashes according to the size of the hotbed or pit.

FRAME-BRIDGE, a bridge built of timbers framed together in such a manner as to obtain the greatest possible amount of strength with a given quantity of material.

The fundamental principle upon which all such construction is based, is that the timbers shall be so arranged that the weight put upon them shall exert a pulling or crushing strain, instead of a transverse strain, and if possible, that the greatest strain shall act as a direct pull in the direction of the fibres of the wood. The construction of a frame-bridge is very similar to that of a roof, excepting that in the bridge a considerable outward thrust upon the abutments is generally permissible, while the walls of a house will not stand this; and that for the bridge a nearly level way on the top is desirable, while for a roof a steep incline is not objectionable, or is even desirable. Fig. 1 represents a simple and

Fig. 1.

useful form of frame-bridge. It will be seen at once that a weight upon the bridge will exert a pulling strain upon the horizontal timber *ab*, and a crushing strain upon *bc* and *ad*, as well as upon the upper timbers, and that the main support is in *ab*, which must be torn asunder before *ad* and *bc* can be bent or displaced to any considerable extent.

The celebrated frame-bridge of Schaffhausen, constructed in 1757 by Grubenmann, a village carpenter, was built exactly in the manner of a roof with a horizontal pathway superadded. It was composed of two arches, one 193 feet, the other 172 feet span. It was merely laid upon the piers, and did not abut against them to exert any outward thrust, as will be seen by fig. 2. The weight on the bridge is transmitted by the oblique beams, which by analogy we may call *rafters*, to the tie-beam *ab*, where it exerts a

Fig. 2.

horizontal pulling strain. These rafters are framed into the tie-beam so as to abut firmly against it in the same manner as Roof-rafters (see **ROOF**). This kind of frame-bridge is very common in Switzerland, where timber bridges abound; and it has doubtless originated from the fact, that most of the bridges have been built by the local carpenters, who are accustomed to the construction of roofs of considerable span for the commodious square-built wooden cottages with overhanging roofs, so common in that country. Frame-bridges of more complex structure are sometimes built; in some of these, the timbers are framed so as to present an arched form. In these cases, the structure is very similar to those described and figured under **CENTERING**. The serious defect of all such bridges is their liability to decay from exposure to moisture, &c., especially at the joints, where water is apt to lodge and remain, from want of free circulation of air to evaporate it. In the bridge of Schaffhausen above described, it was found that when it had stood but 26 years, the oak-beams, where they rested on the masonry at *a* and *b*, fig. 2, were rotted and the frames began

to settle. This was remedied by a carpenter named Spengler, who raised the whole structure upon piles by means of screw-jacks, and replaced the decayed wood. Means should be adopted to admit the free circulation of air in those parts where the timber rests upon the masonry, and to prevent water from settling in the timber joints. The covered bridges of Lucerne and other parts of Switzerland are well known as objects of special interest to tourists, who usually imagine that the roofs are made for the comfort of travelers, but their main object is the preservation of the bridge.

FRAMING, the jointing, putting together, or building up of any kind of artificers' work. The framing of timber generally is described under **CARPENTRY**, and special kinds of framing under **CENTERING**, **DOOR**, **FLOORS**, **FRAME-BRIDGE**, **PARTITIONS**, **ROOFS**, &c. In such trades as mathematical, optical, philosophical, and other complex instrument-making, the workmen who does flat-filed work, and fits all the parts, and puts the whole instrument together, is called the *framer*, and his work *framing*.

In the watch-trade, the man who frames all the parts together, and builds up the watch, is called a *finisher*, and his work is called *finishing*, though it corresponds with what is called framing in other trades.

FRA'MLINGHAM, or 'Strangers' Town,' a town in the east of Suffolk, on the left bank of the Ore, 14 miles north-north-east of Ipswich. It consists of a large market-place, from which a few streets irregularly branch out. The church is built of black flint and stone, and contains the monuments of Thomas Howard, third Duke of Norfolk, and of his duchess, and of the unfortunate Henry Howard, Earl of Surrey, and of his countess. Here are the remains of a castle with thirteen square towers, where Queen Mary retired after the death of her brother, Edward VI. Pop. (1871) 2569.

FRANC, a French silver coin and money of account, which (since 1795, when it supplanted the *livre Tournais*) forms the unit of the French monetary system, and has also been adopted as such by Belgium and Switzerland. The franc is coined of silver, nine-tenths fine, and weighs five grammes, its value being about 94*d*. One pound sterling = 25.2 francs. The franc is divided into 100 centimes, but the old division into 20 sous is still made use of in common life. There are in France silver coins of 1, 2, 5, 10, 20, and 50 centimes; and gold pieces of 20 and 40 francs. Italy has also adopted the French money-system, only that the franc is called *Lira nuova*.

FRANCAVI'LLA, a town of Italy, in the province of Lecce, is situated on an elevation 22 miles south-west of Brindisi. It is well built, has a college, three hospitals, and several convents; has manufactures of woollens, cottons, and earthenware, and, with its dependent villages, has a population of 17,300.

FRANCE, the most westerly portion of Central Europe, extends from 42° 20' to 51° 5' N. lat. and from 8° 15' E. long. to 4° 54' W. long. It is bounded on the N. by the Channel and the Straits of Dover, which separate it from England, by Belgium, the grand duchy of Luxembourg, and the Rhenish provinces of Prussia; on the E. by the lately annexed German provinces of Alsace and Lorraine, by several of the Swiss cantons, and by Italy; on the S. by the Mediterranean and the dominions of Spain, from which it is separated by the Pyrenees; and on the W. by the Atlantic (the Bay of Biscay). The greatest length of F., measured from Dunkirk in the north to the Col de Falguères in the south, is about 620 miles; and its greatest breadth, from east to west, measured from the new boundary, line in the Vosges to Cape St. Matthieu, in Finisterre, is about 550 miles. Its circumference, inclusive of sinuosities, is estimated at nearly 3100 miles, or 5000 kilometres, of which nearly the half is composed of maritime coast-lines, which are subdivided in the proportion of about 600 kilom. on the Mediterranean, 950 kilom. on the Atlantic, and about 940 kilom. on the northern frontiers.

The superficial area of F., including the two Savoy provinces, and Corsica, a department of the republic, but excluding the departments of the Bas-Rhin and the other territories lost to F. by the treaty of peace concluded with Germany in 1871, is reckoned at about 204,000 sq. miles. The possessions of F. which are situated in non-European parts of the world, have a total superficial area of 240,000 square miles. Algeria, with its 122,500 square miles, is here included; but in French official statistics, Algeria is ranked separately from the other colonies as a more immediate dependency. F. is divided into eighty-seven departments, most of which have been named from the rivers or mountains by which they are intersected. The foregoing table gives the names of the ancient provinces of F., with the corresponding departments, their chief towns, areas in hectares, and the population for 1872. The pop. of F., exclusive of Algeria and the colonies, was found by the census of 1881 to amount to 37,321,186.

New Caledonia.....	900,000	41,000

The total superficial area of the French colonies, including Algeria, and reckoning the districts under French protection, is estimated, as has been said, at 240,000 square miles, and the population at about 6 millions; but of the latter number the great majority are natives and savages, or belong to only half-civilized races. The methods employed in taking the census vary, moreover, in the different colonies. To the above-mentioned dependencies has to be added the regency of Tunis, which in 1881 concluded with France a treaty by which it became practically a French protectorate. Tunis has an area of about 45,000 sq. m., and a pop. of 2,100,000.

Population.—The population of F. has not exhibited the same rate of increase as other first-class European powers during the present century, for while the population of Great Britain has nearly doubled within the last fifty years, that of F. scarcely shows an increase of 40 per cent. for the same period. In 1875, the birth-rate was only 2·64 per 100 inhabitants, a rate lower than in any other European country.

The following table shows the condition of the population from the beginning of the century to the date of the census of 1876:

Year of Census.	Number of Population.	Annual Increase.
1801.....	27,349,003	149,941
1806.....	29,107,425	351,685
1811.....	30,461,875	90,292
1826.....	31,858,937	279,415
1831.....	32,569,223	171,787
1836.....	33,540,901	194,337
1841.....	34,217,719	135,362
1846.....	35,400,486	236,553
1851.....	35,783,170	76,537
1856.....	36,039,364	51,236
1861.....	37,382,225	268,572
1866.....	38,067,094	136,186
1872.....	36,102,921	
1876.....	36,905,788	128,310

The decline of population between the census of May 1866 and of May 1872 is 1,964,273, of which 1,597,228 is due to the loss of the different territories annexed to the German empire. The remainder is due partly to losses in the war, and partly to an abso-

* From 1871 until 1878, the portion of the department of Haut-Rhin remaining to France was called *Territoire de Belfort*. Subsequently the old name *Haut-Rhin* has been officially resumed.

By the treaties with Germany of February and May 1871, F. lost 1,447,466 hectares of land, and 1,597,228 inhabitants, comprised within 1689 communes, and distributed over five departments. These losses included the whole of the old department of the Bas-Rhin, two arrondissements with a fraction of the third (Belfort) of the department of the Haut-Rhin, the greater portion of the department of the Moselle, together with a number of cantons and communes in the department of the Meurthe and Vosges. The portions of the two departments of the Meurthe and Moselle remaining to F. have been incorporated into one.

Chief Cities.—The largest cities of France in 1881 were as follows:

Paris.....	2,226,000	Toulouse.....	136,600
Lyon.....	372,900	Nantes.....	122,000
Marseille.....	357,500	St. Etienne.....	120,200
Bordeaux.....	221,000	Rouen.....	104,800
Lille.....	178,000	Le Havre.....	102,600

France has commercial stations on the Gaboon and Ogowe in Africa, four stations on the Red Sea, and in 1882 was establishing stations on the Congo and on the Somali coast, and was making claims to the protectorate of the north-west coast of Madagascar. Its recognized foreign dependencies without Tunis, are as below:

	Area in Hectares.	Population in 1876
In Africa—		
Algeria.....	32,000,000	2,870,000
Senegal and its Dependencies.....	undefined	200,000
Ile de Réunion and Ste Marie.....	250,000	180,000
Nossi-Bé and Mayotte.....	50,000	20,000
In Asia—		
East Indian Possessions.....	50,000	270,000
Cochin-China.....	2,200,000	1,500,000
In America—		
Martinique.....	98,000	165,000
Guadeloupe and its Dependencies.....	165,000	185,000
Guiana.....	1,000,000	27,000
St. Pierre and Miquelon.....	20,000	5,000
In Oceania—		
Marquesas, Tahiti, &c.....	117,000	35,000
New Caledonia.....	900,000	41,000

The total superficial area of the French colonies, including Algeria, and reckoning the districts under French protection, is estimated, as has been said, at 240,000 square miles, and the population at about 6 millions; but of the latter number the great majority are natives and savages, or belong to only half-civilized races. The methods employed in taking the census vary, moreover, in the different colonies. To the above-mentioned dependencies has to be added the regency of Tunis, which in 1881 concluded with France a treaty by which it became practically a French protectorate. Tunis has an area of about 45,000 sq. m., and a pop. of 2,100,000.

Population.—The population of F. has not exhibited the same rate of increase as other first-class European powers during the present century, for while the population of Great Britain has nearly doubled within the last fifty years, that of F. scarcely shows an increase of 40 per cent. for the same period. In 1875, the birth-rate was only 2·64 per 100 inhabitants, a rate lower than in any other European country.

The following table shows the condition of the population from the beginning of the century to the date of the census of 1876:

Year of Census.	Number of Population.	Annual Increase.
1801.....	27,349,003	149,941
1806.....	29,107,425	351,685
1821.....	30,461,875	90,292
1826.....	31,858,937	279,415
1831.....	32,569,223	171,787
1836.....	33,540,901	194,337
1841.....	34,217,719	135,362
1846.....	35,400,486	236,553
1851.....	35,783,170	76,537
1856.....	36,039,364	51,236
1861.....	37,382,225	268,572
1866.....	38,067,094	136,186
1872.....	36,102,921	
1876.....	36,905,788	128,310

The decline of population between the census of May 1866 and of May 1872 is 1,964,273, of which 1,597,228 is due to the loss of the different territories annexed to the German empire. The remainder is due partly to losses in the war, and partly to an absolute decrease in the population of 73 departments. Between 1872 and 1876 there was a decrease in 20 departments, most of all in Seine-et-Oise.

Coast, Islands, and Frontier.—The north-north-west coast is generally irregular, indented with numerous bays, the principal of which is the Bay of St. Malo, the archipelago of Brehat, &c. The west-south-west coast is more lofty and precipitous, and is interspersed with isolated rocks and promontories; while south of the Loire it is low, and lined with salt marshes to the foot of the Pyrenees, where it again assumes a rocky character. Here lie the islands of Ushant (Ouessant), Belleisle, Noirmoutier, Isle d'Yeu, Ré, Oléron, &c. The coast of the Mediterranean, which is broken by lagoons or shore-lakes, is low till it has passed Toulon, after which it becomes bolder. The only islands off the shore are the Hyères, near Toulon; the larger island of Corsica (q. v.) lies north of Sardinia. The Mediterranean here forms two bays or gulfs, as

the Gulf of Lyons and the Gulf of Genoa, which belongs only in part to France.

The land frontiers of F. are formed on the side of Spain by the Pyrenees; on that of Italy and Switzerland, by the Alps and Jura chain; on the north-east, the frontier line is unprotected by natural boundaries, and since the loss of Alsace and Lorraine is no longer defended, as before the war of 1870-1871, by strong fortresses.

Plains, Mountains, and Rivers.—The chief plains are those of Burgundy, and of the oceanic district, embracing the lower basins of the Seine, Loire, and Garonne. France has four great mountain chains—the Pyrenees (q. v.), which separate the French territory from Spain; the Cevenno-Vosgian range, formed of the Cevennes (q. v.), running east and west between the Rhone and Loire, and the Vosges, running north and south between the Moselle and the new boundary line; the Alps (q. v.), which separate the Swiss territory from the provinces of Savoy and Nice; and the Sardo-Corsican range, which belongs, as the name implies, to the islands of Sardinia and Corsica. The highest peaks in the Pyrenees are the Maladetta and Mont Perdu (10,886 feet and 10,994 feet); in the Cevenno-Vosgian range, the greatest height (the Widderkalm) does not greatly exceed 7000 feet. The French portion of the Alps now includes several of the highest mountains and most elevated passes of the range, as Mont Blanc, 15,744 feet; Mont Iseran, 13,272 feet; Mont Cenis, 11,457 feet; and the pass of Little St. Bernard, 7190 feet, &c. In Corsica, the highest peak rises to an elevation of 9000 feet. The grand water-shed of F. is the Cevenno-Vosges chain, which determines the direction of the four great rivers, the Seine, the Loire, the Garonne, and the Rhone; the first three of which flow north-west into the Bay of Biscay or the English Channel, and the fourth into the Gulf of Lyons. Besides these, the more important streams are the Moselle, Meuse, and Scheldt or Escaut (all of which soon leave France, and flow into the Netherlands, or Germany); the Somme and Orne (belonging to the basin of the Seine); the Vilaine and the Charente (belonging to the basin of the Loire); the Oise, the Aube, the Yonne, and the Marne, which are the chief affluents of the Seine; the Sarthe, the Loiret, the Allier, and the Maine, of the Loire; the Dordogne, the Lot, the Tarn, and the Adour, of the Garonne; and the Saône, the Isere, and the Durance, of the Rhone.

The entire extent of river navigation in F. amounts to 5500 miles, or 8,900,000 metres, while the 99 larger canals, which have been constructed either to connect these river-courses or to supply entirely new channels of water-communication, extend over a length of 2900 miles, or 4,700,000 metres. The most important of these works are the canals connecting Nantes, and Brest, and the Rhone with the Rhine, and those of Berry, Nivernais, and Bourgogne. F. possesses only one lake of any importance. Le Grand-Lieu, a little to the south of Nantes, which has an area of about 14,300 acres; but the country abounds in salt marshes or ponds, more especially in the districts of Gascony, Roussillon, and Languedoc.

F. is peculiarly rich in mineral springs, of which there are said to be nearly 1000 in use. Of these, more than 400 are situated in the group of the Pyrenees, where there are 93 establishments for their systematic use. It is estimated that there are, moreover, fully 4000 springs not hitherto employed.

Geology, &c.—F. presents a great variety of geological formations, but although we meet with an almost complete succession of all the stratified and non-stratified formations, they are distributed with great inequality. Thus, for instance, while nearly one-third of the soil is composed of tertiary formations, a mere fractional part only is made up of coal-beds. A belt of primary rocks, forming the skeleton of some portions of the Vosges, Alps, and Pyrenees, and of the great plateaux of Brittany and La Vendée, encircles the great central basin in which rises the volcanic formation of the mountains of Auvergne, with their extinct craters, lava-streams, &c. The spaces between this external breast-work and its volcanic nucleus is occupied by secondary and tertiary formations. Alluvial deposits are met with in all the valleys, but they occur in extensive beds only in the neighborhood of Dunkirk and Niort, and on the borders of the Mediterranean. According to M. Maurice Block's estimate, the physical and agricultural character of the soil of F. may be comprised under the following heads:

	Hectares.
Mountainous districts, heaths, and commons..	9,944,839
Rich land	7,276,369
Chalk or lime districts	9,788,197
Gravel, stony, and sandy	15,951,618
Clay, marshy, miscellaneous	9,807,577
	52,768,600

The same writer further subdivides the soil of F. according to its actual employment under the following heads:

Per cent. of
the whole area

Arable lands	48.3
Meadow lands	9.7
Vineyards	3.7
Cultivated lands	17.8
Roads, streets, public walks, &c.	3.7
Forests and unproductive lands	16.8

Climate.—F. possesses one of the finest climates in Europe, although, owing to its great extent of area, very considerable diversities of temperature are to be met with; thus, for instance, the north-east parts of the country have a continental, and the north-west parts an oceanic climate, resembling those of Germany and Great Britain; while the Mediterranean districts are exposed at times to the ravages of the burning winds which have passed over the deserts of Africa, and to the destructive north-west wind known as the *mistral*, which often does great injury to the fields near the mouths of the Rhone and Var. The mean annual temperature of different parts of F. has been estimated as follows by Humboldt: Toulon, 62° F.; Marseille, 59.5°; Bordeaux, 56°; Nantes, 55.2°; Paris, 51.2°; Dunkirk, 50.5°.

Products.—Of the vegetable products of F., which, from varied climatic and geognostic relations, are necessarily characterized by great abundance and diversity, the most generally cultivated are the cereals, the vine, chestnuts, olives, culinary fruits and vegetables, hops, beet-root for the manufacture of sugar, tobacco, madder, chicory, flax, &c. The dairy industry has progressed of late very rapidly. In 1833 France imported 1,200,000 kilogrammes of butter, and exported only 1,000,000. Since 1880, she exports from 34 to 35 millions of kilogrammes per annum, and receives in return (especially from England) more than 100 millions of francs. Wheat is largely imported, though its cultivation has increased during the last fifty years; that of rye, barley, and maize has exhibited little variation; while the growth of potatoes has been most extensively augmented during the same period. The following table shows the fluctuations to which these alimentary substances have been subjected:

EXTENT OF LAND OCCUPIED IN 1815, 1830, 1845 AND 1869.

	1815. Hectares.	1830. Hectares.	1845. Hectares.	1869. Hectares.
By Wheat	4,591,677	5,011,704	5,743,136	6,900,000
" Rye	2,500,000	2,500,000	2,500,000	2,100,000
" Barley and Oats	1,100,000	1,100,000	1,200,000	1,400,000
" Maize	514,513	593,000	730,000	600,000
" Potatoes	600,000	800,000	925,000	100,000

QUANTITY YIELDED IN 1815, 1830, 1845, AND 1869.

	1815. Hectolitres.	1830. Hectolitres.	1845. Hectolitres.	1869. Hectolitres.
By Wheat	39,460,971	52,782,098	71,963,280	108,000,000
" Rye	25,700,000	32,440,000	30,000,000	24,000,000
" Barley and Oats	14,600,000	17,600,000	18,400,000	90,000,000
" Maize	5,630,000	6,600,000	8,000,000	10,000,000
" Potatoes	21,600,000	54,835,167	77,900,000	100,000,000

The mean annual yields of these productions may be estimated as follows: Wheat, 73,000,000 hectolitres; rye, 22,000,000 hectolitres; barley and oats, 40,000,000 hectolitres; maize, 9,100,000 hectolitres; potatoes, 95,000,000 hectolitres.* The subdivision of farms, the short leases (of less than 10 years) on which the majority are let, and the small number of the great land-owners who reside on their estates, have hitherto tended to check the progress of agriculture in France. Agricultural exhibitions have been held since 1850; 360,000 francs are annually given in prizes, &c.; and there are now nearly one thousand agricultural associations in different parts of France.

The manufacture of sugar from beet-root, which took its origin during the great wars of the early part of the century, has been prosecuted with much vigor during the last 50 years, and about 150 millions of kilogrammes† are annually manufactured. Since the appearance of the vine-disease, beet-root has been extensively employed in the manufacture of alcohol. In 1873, there were 415,204,000 kilogrammes of beet-root sugar produced. The cultivation is almost limited to the north and east; hemp and flax are grown chiefly in the northern, but also in the south-western departments.

The entire production of hemp was estimated in 1842 at 67,507,076 kilogrammes, worth 86,287,300 francs; and that of flax at 36,875,400 kilogrammes, worth 57,507,400 francs. Since that period, there has been little difference in the home production, but an enormous increase in the importation of foreign flax and hemp; the value of the hemp (not to speak of jute) imported in 1873 amounting to 16 millions of francs, and of the flax, 76,700,000 francs. The cultivation of the mulberry-tree derives importance from its bearing on the production of silk. In 1858, the

* The hectolitre equals 2.75 bushels.

† The kilogramme equals 2.2 lbs. avoirdupois.

department du Gard had monopolized nearly half the culture of these trees, which in its aggregate amount has continued unchanged. From its connection with the mulberry, we here refer to the production of silk, which began at the opening of the 17th c., and which in 1790 had reached such vast dimensions that the produce at that period was already 6½ million kilogrammes of cocoons, worth 16½ million francs. Since that period, it has exhibited great variations. From 1840 to 1853, the production continued steadily to increase from 17 to 26 millions of kilogrammes; but the diseases to which the silkworm has been liable since that period reduced the yield of silk to so great an extent, that in 1857 it scarcely amounted to 7 millions of cocoons. The disease gradually abated; still, in 1876, the production of cocoons fell to 2½ millions of kilogrammes, rising again in 1877 to near 12 millions (value 57 millions of francs). The exports of silk and silk manufactures in 1880 from France to the United Kingdom alone had a value of more than £10,000,000.

The vine has, from a very early period, constituted one of the principal sources of the agricultural wealth of France. The choicest wines are grown in the Bordelais, Burgundy, and Champagne, but some excellent kinds are produced on the banks of the Loire and in some of the southern departments. The breadth of soil devoted to this culture fluctuates, but may be stated at about 2,000,000 hectares. The mean produce for every hectare was, in 1788, 21 hectolitres 21 litres; in 1829, 27 hectolitres 20 litres; in 1850, 32 hectolitres 35 litres. Some time ago, the fungus known as the *oidium* attacked the vine, and inflicted such serious damage on the plant, that in 1854 (the worst year), the hectare yielded 5 hectolitres, instead of the average quantity of 23 hectolitres. A new and very destructive vine-disease, occasioned by the ravages of an insect which has been called the *Phylloxera vastatrix*, appeared in the south-east of F. in 1865, and by 1873 had established itself in 12 departments. In 1877, 28 departments had suffered, and in 1880, above 40. The following are annual yields of wine:

	Hectolitres.		Hectolitres.
1808	28,000,000	1874	63,146,000
1829	30,973,000	1877	56,000,000
1848	51,622,150	1880	29,000,000

The average yearly produce of the vineyards of F. is estimated at about 50 millions of hectolitres (about 1000 millions of gallons). Of this, about 1/3 is made into brandy. F. consumes nearly all the wine raised on her soil; the annual exports being on an average little more than 2 millions of hectolitres, valued at about 218 millions of francs.

The principal forest-trees are the chestnut and beech on the central mountains, the oak and cork tree in the Pyrenees, and the fir in the Landes. The destruction of the national forests has been enormous within the last two centuries, but measures have been taken in recent years to plant wood, in order to protect those mountain slopes which are exposed to inundations from alpine torrents, and to provide a supply for the ever-increasing demand of wood for fuel. About one-seventh of the entire territory of F. is still covered with wood. Turf taken from the marshy lands is extensively used, more especially in the rural districts, for fuel.

Animals.—F. is not so well stocked with domestic animals as her great resources might warrant us in assuming that she ought to be. During the 50 years intervening from 1812 to 1862, the numbers of horned cattle were almost doubled in France. In 1872, according to the census report for that year, there were in F., in round numbers, 2,880,000 horses, 500,000 asses, 300,000 mules, 11,000,000 horned cattle, 25,000,000 sheep, 5,000,000 swine, and 2,250,000 dogs. There were in the same year about 2,390,000 hives of bees, valued at about 20 millions of francs; the mean annual returns are, for honey, 6,670,000 kilogrammes, and for wax, 1,620,000 kilogrammes. Poultry constitutes an important item of farm-produce in F., estimated at 45½ millions of francs; while the eggs and feathers yield 35½ millions of francs: the number of fowls in 1872 was 58,000,000. The wild animals are fast diminishing from the soil of F.; the lynx is rarely seen, even among the higher alpine regions, but wolves are still numerous in the mountainous districts of the central departments; while the chamois and wild-goat, as well as the marmot, ermine, and hamster, are found among the Pyrenees, Alps, and Vosges. The wild-boar, roebuck, fox, squirrel, polecat, and marten are to be met with in the woods. The red and fallow deer are scarce; hares and rabbits abound, and game generally is plentiful. The wanton destruction of small (singing) birds having been found to be conducive to the excessive increase of noxious insects, stringent municipal enactments are now being put into force for the protection of those birds.

Fisheries.—The French government expends between three and four millions of francs annually in aiding those engaged in the great fisheries. The value of the exports of fish from F. (12 millions of francs) is little more than half the value of the imports. There are no official reports of river and other fresh-water fishing in F., or of the minor fisheries carried on along the coasts, which

constitute the principal means of occupation and support of the majority of the local population. Pilehards and mackerel are caught in large quantities off Normandy and Brittany. The west coasts have extensive oyster and mussel beds; tunnies and anchovies are caught on the shores of the Mediterranean. The total annual value of the French fisheries was given in 1881 at £3,250,000. French boats fish in the North Sea and along the English east coast; at the Newfoundland fisheries; and off the coast of Iceland. Pisciculture (q. v.) is successfully prosecuted in France. About 85 per cent. of French oysters are derived from four or five breeding grounds. Nearly 100 millions of oysters are annually produced.

Mineral products.—The chief mineral products of F. are coal and iron, on which about 250,000 men are employed. F. possesses several very considerable coal-beds, situated principally in the east-south-east and north. The supply hitherto has not equalled the demand; although in several years of the decade 1870—1880, it rose to the enormous amount of 170 millions of quintals.* Notwithstanding this home-supply, it was found necessary to import many millions of quintals to meet the increased annual demand, which, before the late war, had risen above 200 millions of quintals, while in 1852 it was still under 120 millions. The iron mines of F. are of excellent quality, but their distance from the fuel necessary for the working of the mineral renders them of relatively small value. In 1879 there were 150 mines in operation, from which 40 millions of quintals were taken; more than half of this quantity being obtained from the five departments of Haute-Marne, Haute-Saône, Cher, Moselle, and Nord. F. imports iron from Switzerland, Germany, Belgium, and England. Argentiferous galena, a little silver and gold, copper, lead, manganese, antimony, and tin occur, but hitherto their working has not proved very productive. The department of Charente-Inférieure yields the largest amount of salt, the mean annual produce being 1½ million of quintals (2½ millions of francs), which is fully one-third of the entire annual produce of the whole country. F. derives about 41 millions of francs from its quarries of granite and freestone, its kaolin, marbles, sands, lithographic stones, millstones, &c. Granite and syenite are found in the Alps, Vosges, Corsica, Normandy, and Burgundy; porphyry in the Vosges, and basalt and lava for pavements in the mountains of Auvergne. Marble is met with in more than 40 departments; alabaster occurs in the Pyrenees; the largest slate-quarries are situated near Cherbourg and St. Lô.

The following list gives an approximative estimate of the value of the chief products of French industry:

	Millions of Francs.
Linen fabrics.....	250
Cotton ".....	650
Wollen ".....	950
Silk ".....	1000
Mixed ".....	330
Jewelry, watchmaking.....	35
Gilt-ware.....	12
Minerals, mines, salt, &c.....	600
Articles of food—as sugar, wines, &c.....	364
Skins, leather, oils, tobacco.....	556
Bone, ivory, isinglass, &c.....	30
Chemical products.....	80
Ceramic arts.....	86
Paper, printing.....	60
Forests, fisheries.....	98

Industry, Trade.—The principal seats of industry are as follows: For textile fabrics, the departments Le Nord, La Sarthe, Maine-et-Loire, Seine-Inférieure, Le Calvados, Seine-et-Oise, Ile-et-Vilaine, &c. F. stands unrivalled for her silk manufactures, the finest of which are at Lyon, Tours, and Paris; while St. Etienne is the special seat of the ribbon trade. Alençon, Baillén (fabricating the so-called *Valencienne*), Lille, Arras, Caen, and Bayeux are all famous for their laces and blonds, which alone occupy 250,000 persons. Rheims stands conspicuous for its *merinos* and fine flannels; Amiens and Nancy for their fine printed woollen goods; Lodève and Elbeuf for army cloths. Gloves are made at Grenoble, Paris, &c.

The best carpets are made at Aubusson, Abbeville, and Amiens. Paris is the seat of industry for some of the most costly fabrics, as Gobelin tapestry, shawls of great value, watches, clocks, articles of *vertu*, carriages, philosophical instruments, &c. Sèvres stands unrivalled for its china and glass. St. Gobain and St. Quirin manufacture looking-glasses of the largest size.

The trade of F. is inferior only to that of England and the United States. The great emporiums of trade are Paris, Lyon, St. Etienne, Lille, Rheims, Nîmes, Toulouse, St. Quentin, Orleans, Avignon, Montpellier, &c.; and the most active maritime ports are Marseille, Cette, Havre, Bordeaux, Nantes, Rouen, Calais

* The quintal equals 1·97 cwt.

Dunkirk, Boulogne, Dieppe, &c. These centers of trade have all suffered at different periods during the present century, from the political disturbances under successive governments; but notwithstanding these drawbacks, the commercial activity of the country had made rapid strides within the last 30 years before the war of 1870-1871. The following table shows the value of the total imports and exports of France in millions of francs during the five years preceding 1880:

Years.	Imports.	Exports.	Total.
1876.....	3988	3575	7563
1877.....	3756	3484	7240
1878.....	4460	3369	7829
1879.....	4594	3163	7757
1880.....	4907	3400	8307

The total exports from France (without counting her colonies) to Great Britain in the years 1876-1880 varied from £45,823,324 (1147 millions of francs) in 1877, to £38,459,096 (961 millions of francs) in 1879; while the imports into France from Great Britain ranged from £29,000,273 (725 millions of francs) in 1876, to £26,558,333 (664 millions of francs) in 1879. France, with her colonies, is reckoned the second best customer of England. The staple exports from France to the United Kingdom are, in order of importance: silk manufactures, woollen manufactures, sugar, butter, wine, leather manufactures, eggs, brandy; and these constitute two-thirds of the exports hitherto. The staple imports of British produce into France are woollen manufactures, cotton manufactures, coals; and these constitute the bulk of the imports. The others, including wrought iron and copper, have an annual value of not more than half a million sterling.

The merchant navy of France numbered, in 1880, 15,058 vessels of 919,293 tons. Of 36,425 large vessels, with a tonnage of 11,963,346 tons, that entered French ports in 1880, 10,194 sailed under the French flag. The *cabotage*, or internal and coasting traffic, is a great source of financial wealth to the state, to which all rivers and canals belong.

Railways, &c.—According to the official report, the railways, in operation in the year 1881 measure 26,000 kilomètres, or 16,250 miles. With the exception of about 200 miles, the railways of F. are held by six companies, which are under the superintendence of the state, from which they receive subsidies of about 500,000,000 francs. In 1880 their earnings were as follows:

	Francs.
Paris-Mediterranean.....	329,522,062
Paris-Orleans.....	167,074,763
Northern.....	147,015,262
Western.....	125,731,612
Southern.....	92,177,642
Eastern.....	120,360,876

The total receipts of all the lines were, for 1858, 334,769,469 francs; number of passengers conveyed by rail 37,952,398. In 1865, the number was 81,533,061; and in 1869, 111,164,284. In 1882, the profits on government lines was 3,500,000 francs. By a clause in the treaty of 1871, the whole of the lines in the Eastern Company in Alsace-Lorraine, about 700 kilomètres in length, were sold to the imperial government of Germany for 325 millions of francs.

The creation of the first highroads in F. is referred to Philippe Auguste; and their more perfect organization in the 16th and 17th centuries, to Henry IV. and Louis XIV. Under Napoleon I. there were 125 highroads, extending in all over 30,000 kilomètres; and at the present time there are upwards of 600 national roads (35,000 kilom.), 265,000 departmental roads (45,000 kilom.).

Postal Service.—The postal service in F. goes back to the year 1464, when Louis XI. placed it under the direction of the state. Since 1849, a system of low prepayment for letters has been established. At the present time, letters weighing from under 10 to under 100 grammes require stamps from 15 centimes to 1 franc 20 centimes, according to weight. The whole receipt of the postal service for the year 1879 was 104,770,000 francs; while, for 1869, before the war, it was 94,199,359 francs; the expenses in the meanwhile have risen from 63 million francs in 1869, to above 76 millions of francs in 1879.

Electric Telegraphs.—The first electric telegraph was constructed in F. in 1844, and F. is now intersected by a close network of wires, which flash communications between Paris, as the central focus, and every part of the empire. In 1880, there were 41,220 miles of lines, including submarine and subterranean lines. The number of inland telegraphic messages sent in 1880 was 14,914,940, and 157,895 international telegrams.

Constitution, Government.—On September 4, 1870, the emperor, Napoleon III., was declared to be no longer the head of the state, and France was proclaimed a republic. At the close of 1872, the supreme power was vested in a National Assembly, with whom rests the nomination of the chief officer of the state, bearing the title of 'President of the French Republic;' and nominated for seven years. This officer, as chief of the executive power, but

under responsibility to the National Assembly, is authorized to promulgate and insure the proper execution of all laws and ordinances transmitted to him by the president of the Assembly. By the law of February 25, 1875, the National Assembly is to consist of two bodies—the Chamber of Deputies and the Senate. The members of the former are elected by universal suffrage; the senate consists of 300 members, of whom 225 are elected by the departments and colonies, and 75 by the National Assembly. The budget for 1882 was charged 11,374,990 francs for the administrative expenses of the National Assembly and the authorized indemnities of the deputies.

To the President of the Republic belongs, in accordance with the principles that have regulated the respective domains of legislative and executive power in F. under all forms of government, the right of appointing the judges, commanding the forces, and maintaining relations and settling treaties with foreign states, in respect to which acts he is responsible to the assembly. He appoints and dismisses the ministers of state, who are also responsible to the assembly, and he may reside at the seat of the National Assembly, and, provided he gives notice of his intentions, may take part in its deliberations. His salary was fixed in 1873 at 600,000 francs (£24,000), with an extra allowance of 162,000 francs for household expenses. The office of president was held till 1873 by M. Thiers; from 1873 till 1879 by Marshall MacMahon; and thereafter by M. Grévy.

The ministry is presided over by eleven ministers of state, each of whom has a definitely limited sphere of administrative duty and authority; and in addition, the president is assisted in the government by a Council of State, 'Conseil d'Etat,' which, according to a decree of the National Assembly, is to consist in all of 43 members, 15 of whom may be nominated by the president, while the remaining 28 are selected by the Assembly. The functions of this body are restricted to giving advice on bills presented to the National Assembly by the president or the ministers.

Departments, &c.—F. is at present divided into 86 *departments*, comprising 362 *arrondissements*, 2865 *cantons*, and 35,985 *communes*. Each department is presided over by a *préfet*, nominated by the president of the republic on the presentation of the minister of the interior; each *arrondissement* by a *sub-préfet*; each *canton* by a member at the general council of the *département*, which meets annually for whatever period may be decreed by the head of the state; and every *commune* has its *maire* and municipal council. Every chief town of a *canton* has its commissary of police; in the larger towns, there must be one of these officers to every 10,000 inhabitants. The administration of justice is presided over by a special minister of state, who is keeper of the seals. A supreme tribunal serves as a court of appeal from the lower courts. The tribunals of commerce and police, together with those of the several departments, take cognizance of the various civil and criminal cases specially falling within their several spheres. There are 357 tribunals of the *arrondissements*, or *tribunaux de première instance*, which are divided into six classes; 2681 police courts; 216 tribunals of commerce; 26 courts of appeal divided into four classes; a *Cour de Cassation*, divided into three chambers, which confirms or annuls the sentences of the police and assize courts; and a *Haute Cour de Justice*, which gives final judgment in all cases of offence against the state. Assizes are held every three months in 59 towns; and, independently of the ordinary judicial magistrates, the courts of assize are composed of juries of twelve men, chosen in accordance with certain prescribed regulations.

In the maritime and commercial towns there were, under the empire, 85 councils of *prud'hommes* (experienced men), with summary jurisdiction in matters to the amount of 200 francs. These councils, which are composed of master-workmen elected annually, decide on cases of dispute, chiefly in regard to questions of wages, and differences between masters and men. The state is charged 35½ millions of francs for the expenses incident to the ministry of justice, according to the budget for 1882. There are 387 departmental prisons, 21 central houses of detention, 2 political prisons at Doullens and Belleisle, and numerous penitentiaries and reformatories for the young. All these prisons, excepting the two for political offenders, are in part self-supporting. The only hulks, *bagues*, still remaining are at Toulon, where convicts of a certain class undergo their sentences, but the principal penal settlement is in French Guiana (q. v.).

Religion, Churches.—No person can be molested in F. on account of his religious opinions, provided the manifestation of them does not disturb the public peace as established by law. The public exercise of any special form of religion must, however, be preceded by the official authorization of the *préfet*, or in special cases, by higher authority. The recognized forms of faith are—the Roman Catholic, the Protestant (including the Reformed and Lutheran), the Jewish, and, for Algeria, the Mohammedan. The clergy attached to these religions receive their pay from the state, and are exempt from military service. The Roman Catholic

Church embraces the great majority of the people. Of the 37,000,000 which constitute the present population of F., 1,500,000 appertain to the two Protestant churches, 150,000 to the Jewish persuasion; and 25,000 to non-recognized but tolerated denominations, the Anabaptists comprising nearly one-third of this number.

At the breaking out of the Revolution, the annual revenues of the church amounted to 150,000,000 of livres, and its debts to 133,000,000. The state appropriated to itself the funds of the church in 1879, and assumed the responsibility of maintaining public worship. The following table gives a summary of the expenses incurred by the state for the maintenance of religion since the Consulate.

Years.	Catholic Religion.	Protestant Church.	Jewish Form of Faith.	Moham. Rel. in Algeria.
	Francs.	Francs.	Francs.	Francs.
1803.....	4,059,006	22,363		
1813.....	16,628,868	695,000		
1823.....	26,138,445	577,829		
1835.....	33,523,319	849,763	79,995	3,000
1847.....	37,630,008	1,240,229	108,836	3,000
1854.....	42,223,329	1,328,891	149,428	568,024
1859.....	44,994,100	1,408,436	189,400	630,200
1873.....	51,500,000	1,400,000	273,000	500,000

The archbishops and bishops of the church of F. are to be nominated by the President of the Republic, and canonically inducted by the pope. There are 88 Roman Catholic prelates—18 archbishops, and 70 bishops. The archbishop of Paris receives 50,000 francs per annum; the other archbishops, 20,000 francs; the bishops, 15,000 francs. Six French prelates hold the rank of cardinals, to which dignity they are nominated by the pope on the presentation of the president. Every archbishopric has 3, and every bishopric 2 vicars-general, the whole number being 190. Their salaries vary from 3500 to 4500 francs. There are 709 canons belonging to the various cathedral chapters, receiving from 1600 to 2400 francs per annum; 3437 curés or parochial beneficed clergy, who are canonically inducted by the bishops, under the approval of the state; and 31,586 curates or *desservants*. The curés receive from 1200 to 1500 francs; the curates, 200 francs. The curés may be assisted by a certain number of vicariats, who receive from 350 to 500 francs; there are at present 9000 authorized by the state. There are in F. 105 Reformed consistories, and 44 belonging to the Lutheran Church. The central council of the Reformed churches holds its sittings at Paris. Synods composed of the delegates of five churches may assemble with the authority of the state to regulate the celebration of the services of their church; but their meetings cannot last longer than six days, and their decisions must be submitted for the approbation of the government. There is a Protestant seminary for the Reformed at Montauban. Besides the sums inscribed in the budget for the maintenance of religion, the departments are charged with special annual subsidies, which have risen of late years in a rapid ratio, especially under the empire.

Public Instruction.—Public instruction is presided over in F. by a special ministry. Nearly half the expenses connected with it are defrayed by the state, and the remainder by the departments. There are 15 academies located in the following towns—Aix, Besançon, Bordeaux, Caen, Clermont, Dijon, Douai, Grenoble, Lyon, Montpellier, Nancy, Paris, Poitiers, Rennes, Toulon. These academies are divided into the five faculties of theology, law, medicine, sciences, and literature, and supplemented by various superior and preparatory schools. The professors are paid partly by the state, and partly by fees. There are 81 normal schools intended to train teachers for the higher departments of instruction. Secondary instruction has received an immense impetus during the present century. In 1872, there were 41,800 free and public schools for boys, and 17,500 public schools for the use of girls, and the entire number of scholars exceeded four millions. In 1872, the number of people unable to read or write between the ages of 6 and 20 was 2,082,328; above 20, 7,702,362. The departments share very unequally in the diffusion of education, the census of 1872 showing a percentage of ignorance ranging from 6 to 60 in the 87 departments; and it may be observed that the proportion of the educated is highest in the N. and E. of France.

F. supports numerous colleges and schools for instruction in special branches of knowledge: as L'Ecole des Chartes; des Langues Orientales; des Beaux-Arts, founded in 1671 by Louis XIV.; de Dessin, founded in 1766 by Louis XV.; the Conservatoire de Musique, founded in 1784; L'Ecole de Rome, founded by Louis XIV., and L'Ecole d'Athènes, founded in 1846; L'Ecole des Ponts et Chaussées, for the instruction of engineers of public works; L'Ecole des Mines (1783); the Conservatoire National des Arts et Métiers, for the application of science to the arts and trades; the Central School des Arts et Métiers; and the national

schools for arts and trades. There are numerous agricultural, forest, farming, and veterinary schools, besides the Ecole Polytechnique, specially designed to prepare youths for the public services; and military and naval colleges at St. Cyr, Saumur, Paris, Vincennes, Brest, Toulon, and St. Denis.

Literary and Scientific Institutions.—Among the literary and scientific institutions of F. the first is L'Institut de France (q. v.). The Museum of Natural History, known formerly as the Jardin du Roi, is one of the finest in the world. The Bureau des Longitudes and the Observatoire, at Paris and Marseille, have occupied the first rank among scientific institutions since their foundation. These establishments are all maintained at the cost of the state. Paris possesses several libraries belonging to and supported by the state, but freely opened to the public. The most important of all is that now known as La Bibliothèque Nationale. See LIBRARIES. There are 338 public libraries in the provinces, to all of which access is afforded in the most liberal spirit. F. is rich in public galleries of painting, statuary, and articles of *artu*. The expenses of secondary and primary education, literary and scientific institutions, national archives, &c., are charged in the budget for 1882 at 106,152,000 francs.

Theaters.—The theater, like all other public institutions, is under the surveillance of the state, which contributes to the maintenance of the drama; above 8 millions of francs being inscribed on the budget of 1882 for the support of the fine arts (since 1882 under a separate ministry).

Charitable Institutions.—F. is rich in institutions of charity, many of which are remnants of the old system of church relief; but the *crèches*, of which there are several hundreds, and which are, in fact, free nurseries, are a modern form of charity, which originated (in 1844) with M. Marbeau at Paris. The public hospitals and infirmaries are maintained by special endowments, a percentage on the receipts at theaters and other places of amusement, and by subsidies from the government and local communes. Public charities for the relief of paupers derive their resources either from departmental or municipal funds, and are administered by the *bureaux de bienfaisance*, by the *dépôts de mendicité*, and by numerous other local institutions; besides which, the state contributes between 8 and 9 millions of francs (for 1876, 8,485,810 francs) for charitable purposes.

Taxation Finances.—The public revenues are obtained in F. from direct and indirect taxation, and comprised in the budget, voted by the National Assembly, under the heads of ordinary resources and special resources; the former including direct and indirect taxes, from stamps, the produce of forests, telegraphs, Algeria, &c.; and the latter, departmental funds, special imposts, &c. The following table shows the financial report of the public receipts and expenditure for different years from 1815 to 1881:

Years.	Receipts, in francs.	Expenditure, in francs.
1815.....	743,830,200	798,590,859
1824.....	994,971,962	992,583,233
1830.....	1,031,796,054	1,095,142,115
1840.....	1,234,483,099	1,363,711,102
1850.....	1,431,622,471	1,472,537,238
1859.....	1,766,080,877	1,773,919,114
1871.....	2,190,120,590	2,161,262,952
1881.....	2,762,480,817	2,736,208,789

Public Debt.—In 1812, the date of the Restoration, the interest of the debt was 63 million francs; under the Bourbons it rose to 200 millions; and from 1830 to 1848, Louis Philippe increased it to 244 millions. During the three years of the second republic, 5 millions were paid off; but the second empire (1852—1869) added nearly 120 millions to the annual burden. The increase of the debt during the empire arose from a succession of loans raised by borrowing directly from the mass of small capitalists, without the intervention of large banking-houses. The amount of the national debt of France is very variously given according to what is included under that head; but if we take the funded debt bearing *rentes* or interest, the amount of such *rentes* in January 1870, before the war, is stated at 358 million francs = about £14,000,000, representing a capital of 11,500 million francs, or £460,000,000. The loans and other obligations incurred to meet the expenses of the war of 1870—1871, including the indemnity of 5 milliards of francs to Germany, nearly doubled this sum. The total expenditure arising from the war and the foreign occupation has been finally stated at 9820 millions of francs; yet in spite of this enormous strain on the exchequer, the national wealth of France has increased since the war. In 1876 provision had to be made for paying, as annual interest of the total debt, over 1150 millions of francs. This was calculated to correspond to a capital sum of 23,403 millions (nearly 23½ milliards) of francs.

The continual deficits from the close of the first empire in 1815 to the close of the second empire in 1870, have been covered by loans, bearing interest or *rentes* at the rate of 3, 4, 4½, and 5 per cent. The budgets voted annually by the representatives of the nation have almost invariably shown a small assumed surplus;

while the *compte définitif* for the corresponding period, when published some years afterwards, has without exception exhibited a large deficit. The actual state of accounts with regard to national income and expenditure is not published till after the lapse of six or seven years; so that in 1877 the most recent final account (*budget réglé*) was that for the year 1869.

The following table shows the rate at which the deficits have increased since 1814:

Periods.	Amount of Deficits. Francs.
Bourbon Monarchy, from 1815 to 1830.....	22,550,000
Reign of Louis Philippe, from 1830 to 1848.	997,866,000
Second Republic, from 1848 to 1852.....	359,374,000
Second Empire, from 1852 to end of 1869....	2,138,539,500

The total value of the French money in circulation is 12,630,657,996 francs. According to the act of monetary union effected between France, Belgium, Switzerland, and Italy, the emission of coined pieces is to be at the rate of 6 francs for every inhabitant, which, taking into account the presumed increase of population to the year 1880, when the term of the treaty expires, gives for France the sum of 239 millions; for Belgium 32, for Italy 141, and for Switzerland 17 millions of francs. The amount of specie in reserve in the bank in January 1873, was 790,000,000 francs; the amount of notes in circulation by the bank and its branches was 2,858,619,270 francs. The maximum amount of notes in circulation has been fixed at 3,000,000,000 francs, by the decree of the National Assembly of July 1872.

Army.—Standing armies date in F. from the time of Charles VII. The law of 1832 regulated the system of recruiting by conscription, on the footing which, with few modifications, it has subsequently occupied. By the law of 1872, substitution and enlistment for money are prohibited, and the principle of universal liability to arms is laid down, in accordance with which every Frenchman must be for five years in the 'active army,' for four years in the reserve of the same, for five years in the territorial army, and for six years in the reserve of the territorial army. Besides the ordinary physical causes of exemption, there are various others admitted, arising from family, social, or individual conditions; while, moreover, young men who pass the necessary examination, may obtain exemption by enlisting as volunteers for one year only, and defraying the cost of their maintenance and clothing. The returns for 1871 gave the strength of the French army as follows: Peace-footing—404,192 men; war-footing—757,727 men. In 1881, after extensive reorganization, the total military force of France comprised (1) an active army (including gendarmerie, &c.) of 704,714 men; (2) the reserve of 510,294 men; (3) the territorial army of 582,523 men; (4) the reserve of the territorial army, 625,633 men—giving a total of 2,423,164. The ministry of war required, according to the budget of 1882, a sum of 571,400,000 francs. F. is divided into 18 military commands, or *corps d'armée*, each under a field-marshal, which are subdivided into districts commanded by generals of division, and into lesser circles, corresponding with the departments, and under generals of brigades. The fortified *chefs-lieux* are at Arras, Bayonne, Besançon, Bourges, Brest, Cherbourg, Grenoble, Langres, La Rochelle, Le Havre, Lille, Lyon, Marseille, Montpellier, Nantes, Perpignan, St. Omer, Toulon, and Toulouse. Since the annexation of Metz and Strasbourg by Germany, Avignon, Perpignan, Quiberon, and Rouen have taken their place. The *Garde Nationale* (q. v.), formerly a supplement to the regular army, was created in 1789, but owing to its proved incompetence during the Communistic outbreak in 1871, it was decreed that it should gradually be abolished.

Navy.—In 1881, the French navy numbered 27 vice-admirals (4 in reserve), 35 rear-admirals, 103 captains of first-class men-of-war, 203 captains of frigates, 763 lieutenants, and 374 ensigns. The sailors afloat and on shore numbered 28,500, which, together with engineers, &c., brought the grand total of those employed in the fleet to about 65,000. The inscription for the navy owes its systematic organization to the great minister Colbert (1681). At present, all persons engaged in any maritime avocation between the ages of 18 and 50 are liable to inscription, but the service is only compulsory for three years. There are 170,000 names on the rolls. Of these, 130,000 may be called out in time of war. The fleet consisted in 1881 of 59 iron-clads, 264 unarmored screw steamers, 62 paddle-steamers, and 113 sailing vessels. Amongst these are included torpedo-boats and gun-boats. The iron-clads carry 450 guns. There are 22,400 marines in peace, 28,000 in war, and 25,500 customs and coast-guard men. F. has 6 depôts for marine artillery, 3 foundries, and 2 manufactories for projectiles. There are special hospitals, schools, and libraries for the use of the navy; and 5 maritime districts, subdivided into 12 arrondissements, at which are administrative courts for the settlement of all naval questions.

Money, Weights, and Measures.—For the money, weights, and measures now used in F., see FRANC, METRE, LITRE, GRAMME.

Colonies.—Algeria (which, according to the constitution of 1852, is not a colony, but an integral part of F.) is treated of in a separate article. In the larger French colonies, the administrative power is vested in a governor, who exercises supreme military command, and is assisted by a general council, specially charged to vote the budget of the province. Three officers act under the orders of the governor—viz., the 'ordonnateur,' director of the interior, and procurator-general. There is also in each colony a colonial controller, who presides over the financial and other departments of general administration.

See *Statistique génér. méthodiq. et compl. de la France*, by J. H. Schmitzler *Diction. et Annales de l'Administ. Franc.*; *Bulletin des Lois* (1878); *Statistique de France* (1878); *Dictionnaire général de la Politique*, by M. Maurice Block (1882).

History.—Gallia (Eng. *Gaul*) was the ancient name under which F. was designated by the Romans, who knew little of the country till the time of Cæsar, when it was occupied by the three races of the Aquitani, Celtae, and Belgæ, who respectively inhabited the south-west, the west and central, and the north and north-east parts. There were also some tribes of Germans, Ligurians, and Greeks, but the latter never penetrated far beyond the shores of the Mediterranean, where they planted colonies, the most important of which was Massalia (Marseille). Under Augustus, Gaul was divided into four provinces, which, under subsequent emperors, were dismembered and subdivided into seventeen. In the decline of the Roman power, Gaul was ravaged by neighboring hordes, and in the 5th c. it fell completely under the power of the Visigoths, Burgundians, and Franks. In 486 A.D., Clovis, a chief of the Salian Franks, raised himself to supreme power in the north.

His dynasty, known as the Merovingian, ended in the person of Childeric III., who was deposed, 752 A.D., after the kingly power had already passed into the hands of the former Marie du Palais, Pepin d'Heristal, and, after him, into those of Charles Martel and Pepin le Bref. The accession of Pepin gave new vigor to the monarchy, which, under his son and successor Charlemagne, crowned emperor of the West in 800 (768—814), rose to the rank of the most powerful empire of the West. Christianity, civilization, and letters were protected during his reign, and before his death he had stretched the limits of his empire from the Eider and the German Ocean to the Ebro and the Mediterranean, and from the Atlantic to the Baltic. With him, however, this vast fabric of power crumbled to pieces, and his weak descendants completed the ruin of the Frankish Empire by the dismemberment of its various parts among the younger branches of the Carolingian family. Intestine wars desolated the land, and foreign assailants threatened it on every side. In 911 A.D., the ravages of the Northmen had assumed so persistent a character, that Charles le Simple was glad to purchase immunity from their encroachments by the cession of the territory subsequently known as Normandy. Anarchy reigned paramount; the various governors established an hereditary authority in their several governments, and the crown was by degrees deprived of the noblest part of its appanages. The power of some of the vassals surpassed that of the kings; and on the death of Louis V. the Carolingian dynasty was replaced by that of Hugues, Count of Paris, whose son, Hugues Capet, was elected king by the army, and consecrated at Rheims, 987 A.D. At this period, the greater part of F. was held by almost independent lords, and the authority of the Capetian kings extended little beyond Paris and Orleans. Louis le Gros (1108—1137) was the first of the race who reinstated order. He promoted the establishment of the feudal system, abolished serfdom on his own estates, secured corporate rights to the cities under his jurisdiction, and gave efficiency to the central authority of the crown. A greater degree of general order was thus secured, while a new element in the state was generated by the foundation of a free burgher class. Louis carried on a war against Henry I. of England; and when the latter allied himself with the Emperor Henry V. of Germany against F., he brought into the field an army of 200,000 men, whose ready appearance afforded the first instance of the existence of a common national feeling of patriotism, ready to respond to the appeal of the sovereign. The *oriflamme* is said to have been borne aloft for the first time on this occasion as the national standard. Louis VII. (*Le Jeune*), who took part in the second crusade (1137—1180), was almost incessantly engaged in war with Henry II. of England. His son and successor, Philippe Auguste (1180—1223) recovered Normandy, Maine, Touraine, and Poitou from John of England, and increased the power of the crown in various other parts of France. He took an active personal share in the Crusades, and permitted the pope to organize a cruel persecution against the Albigenses in the southern parts of the country.

Philippe was the first to levy a tax for the maintenance of a standing army, and in his reign a chamber of peers, of six secular and six ecclesiastical members, was instituted, to act as a council of state. Many noble institutions date their origin from this reign, as the university of Paris, the Louvre, &c. By the

amendment of the administration of justice, the right of appeal to the royal courts was established, and the arbitrary power of the great vassals crippled. Improvements in the mode of administering the law were continued under his son, Louis VIII. (1223—1226), and his grand-son, Louis IX. (1226—1270), who caused a code of laws (*Établissements de St. Louis*) to be promulgated. St. Louis also effected many modifications in the fiscal department, and, before his departure for the Crusades, secured the rights of the Gallican Church by a special statute, in order to counteract the constantly increasing assumptions of the papal power. Under his son, Philippe III. (1270—1285), titles of nobility were first conferred by letters-patent. He added Valois and the *comtés* of Toulouse and Venaisin to the crown. Philippe IV. (1285—1314), surnamed *Le Bel*, acquired Navarre, Champagne, and Brie by marriage. With a view of securing support against the secular and ecclesiastical nobility, with whom he was constantly at war, Philippe gave prominence to the burgher element in the nation, and on 28th March 1302, he, for the first time, called together the *États généraux*, or general estates, at which the *tiers état*, or burgher class, appeared together with the nobles and clergy. These changes were, however, accompanied by arbitrary innovations in the fiscal and other departments of the government, which were effected with reckless haste and violence. With a view of securing to the crown the great fiefs, he abrogated the right of females to succeed to landed property. His tyrannical persecution of the Templars showed the extent to which the regal power could be stretched; and under his successors Louis X. (1314—1316), Philippe V. (1316—1321), and Charles IV. (*Le Bel*). (1321—1328), the last direct descendant of the Capetian line, the rule of the kings of F. became even more unlimited, whilst the court was given up to every species of luxurious indulgence known to the age. Philippe VI., the first of the House of Valois (1328—1350), a distant relative of Charles IV., and the nephew of Philippe IV., succeeded in right of the salic law. His reign, and those of his successors, Jean (1350—1364) and Charles V. (*Le Sage*). (1364—1380), were disturbed by constant wars with Edward III. of England, who laid claim to the throne in right of his mother, a daughter of Philippe le Bel. The war began in 1339; in 1346, the battle of Crécy was fought; at the battle of Poitiers (1356), Jean was made captive; and before its final close after the death of Edward (1377), the state was reduced to bankruptcy, the nobility excited to rebellion, and the mass of the people sunk in barbarism.

Falsification of the coinage, onerous taxation, and arbitrary conscriptions, brought the country to the verge of irretrievable ruin, while the victories of England humbled the sovereign, annihilated the French armies, and cut down the flower of the nation. The long and weak minority of Richard II. diverted the English from the prosecution of their groundless claims to the kingdom of F., which revived somewhat from the effect of its long and disastrous warfare; but during the regency for the minor, Charles VI. (*Le Bien Aimé*), (1380—1422), the war was renewed with increased vigor on the part of the English nation, who were stimulated by the daring valor of Henry V. The signal victory won by the English at Azincourt in 1415; the treason and rebellion of the French princes of the blood, who governed the larger provinces; the ambition of the several regents, the ultimate imbecility of the king, the profligacy of his queen, and the love of pleasure early evinced by the dauphin; all combined to aid Henry in his attempts upon the throne. But the premature death of Henry, the persevering spirit of the people, and the extraordinary influence exercised over her countrymen by the Maid of Orleans, concurred in bringing about a thorough reaction, and, after a period of murder, rapine, and anarchy, Charles VII. (*Le Victorieux*) (1422—1461) was crowned at Rheims. He obtained from the Estates General a regular tax (*taille*) for the maintenance of paid soldiers, to keep in check the mercenaries and marauders who pillaged the country. The policy of his successor, Louis XI. (1461—1483), the first king entitled 'His most Christian Majesty,' favored the burgher and trading classes at the expense of the nobles, while he humbled the power of the crown-princes. He was a crafty ruler, who managed the finances well, and succeeded, by policy and good-luck, in recovering for the crown the territories of Maine, Anjou, and Provence; while he made himself master of some portions of the territories of Charles the Bold, Duke of Burgundy. Charles VIII. (1483—1498), by his marriage with Anne of Brittany, secured that powerful state and consolidated the increasing power of the crown. With him ended the direct male succession of the House of Valois. Louis XII. (1498—1515), (*Le Père du Peuple*) was the only representative of the Valois-Orleans family. The tendency of his reign was to confirm the regal supremacy, while the general condition of the people was ameliorated. He and his successor, Francis I. (1515—1547), of the Valois-Angoulême branch, wasted their resources in futile attempts to establish their hereditary claims to Lombardy, and were thus perpetually embroiled with the House of Austria. A concordat with the pope, signed in 1516, secured the nomination of the Gallican bishops to the king. In this reign, the Assembly

of Notables and Deputies superseded the General Estates. The defeat of Francis at the battle of Pavia, in 1525, and his subsequent imprisonment at Madrid, threw the affairs of the nation into the greatest disorder, and embarrassed the public finances to a most ruinous extent. Arts and literature were encouraged in this reign, and in that of the succeeding monarch, Henri II. (1547—1559), who continued the disastrous Italian war. In the latter reign began the persecutions of the Protestants, which were carried on with still greater cruelty under Henri's three sons, Francis II. (1559—1560), Charles IX. (1560—1574), and Henri III. (1574—1589), the last of this branch of the Valois.

The massacre of St. Bartholomew (1572) was perpetrated under the direction of the queen-mother, Catharine de' Medici, and the confederation of the League, at the head of which were the Guises. The wars of the League, which were carried on by the latter against the Bourbon branches of the princes of the blood-royal involved the whole nation in their vortex. The succession of Henri IV. of Navarre (1589—1610), a Bourbon prince, descended from a younger son of St. Louis, allayed the fury of these religious wars, but his recantation of Protestantism in favor of Catholicism, disappointed his own party. The early part of his reign was perpetually disturbed by the mutinies of the troops and the rebellions of the nobles. By degrees, however, Henri, through the astute counsels of his minister Sully, and by his own personal popularity, raised the power of the crown higher than ever, while he began a system of thorough administrative reform, which was only arrested by his assassination by the fanatic Ravaillac. During the minority of his son, Louis XIII. (1610—1643), Cardinal Richelieu, under the nominal regency of Marie de' Medici, the queen-mother, ruled F. with a firm hand, although his oppression of the Protestants at home, and his co-operation with them abroad, in endeavoring to humble the House of Austria, entailed long and costly wars with little fame on France. Cardinal Mazarin, under the regency of the queen-mother, Anne of Austria, exerted nearly equal power for some time during the minority of Louis XIV. (1643—1715). The wars of the Fronde, the misconduct of the parliament, and the humbling of the nobility, gave rise to another civil war, but with the assumption of power by young Louis, a new era commenced, and till near the close of his long reign, the military successes of the French were most brilliant, and the boundaries of F. were enlarged very nearly to what they were before the war of 1870—1871. The military glory of the kingdom was maintained by a host of gallant commanders, amongst whom stood conspicuous the names of Turenne, Vauhan, Luxembourg, Catinat, Vendôme, Boufflers, and Créquy, while, by the far-sighted policy of the minister Louvois, a well-organized army and a newly-created navy made the power of F. formidable to all neighboring nations. The progress of the people in the arts of peace was not less marked. At the close of his rule, the oppressive war-taxes, the prodigality of the court, the luxurious lives of the clergy, and the absolutism and bigotry of the aged monarch, combined to undermine the foundations of national prosperity and freedom, and at his death the state was left trammelled with a debt of 3500 millions of livres, and his youthful heir Louis XV. (1715—1775), succeeded to a heritage whose glory was tarnished, and whose stability was shaken to its very foundations. The long inglorious reign of Louis XV. presents nothing worthy of notice except the gradual rise of those sentiments of infidelity and license which prepared the overthrow of all the ancient institutions of the country. The regency of the profligate Orleans paved the way for the miseries which followed, while his corrupt financial administration brought the nation into the most overwhelming monetary embarrassments. In this reign, Corsica was added to France.

The thorough disorganization of the state, and the neglect of the fleet and army, prevented all attempts at conquests either on sea or land. The colonies were left a prey to the attacks of other powers, while the capricious change of policy which the king's mistress, Madame Pompadour, forced upon the government, brought contempt upon the country. The peace of Paris, 1763, by which the greater portion of the colonial possessions of F. were given up to England, terminated an inglorious war, in which the French had expended 1350 millions of francs. The close of this unhappy reign was still further disturbed by the cabals of the Jesuits, who were finally banished in 1764. In 1774, Louis XVI., a well-meaning, weak prince, succeeded to the throne. His first ministers, Maurepas, Turgot, and Malesherbes, had not the vigor to carry out the reforms which their sense and patriotism suggested to them, and they were soon compelled to yield to the intrigues of the nobility, and resign their places. They were succeeded by the financier Necker, who endeavored, by economy and method, to arrest the impending bankruptcy of the state, and succeeding ministers made futile attempts to diminish these financial disorders by new forms of taxation, which were generally opposed either by the assembly or the court. The American war of freedom had disseminated republican ideas among the lower orders, while the Assembly of the Notables had discussed and made

known to all classes the incapacity of the government, and the wanton prodigality of the court. The nobles and the *tiers état* were alike clamorous for a meeting of the States; the former wishing to impose new taxes on the nation, and the latter determined to inaugurate a thorough and systematic reform. After much opposition on the part of the king and court, the *Etats Généraux*, which had not met since 1614, assembled at Versailles on the 25th of May 1789.

F. was at that moment ripe for a revolution. Although the nobility was exceedingly numerous (as not only did the children of a noble belong to this class, but its numbers were constantly being increased by creation), there were great differences in the rank and dignity attached to the order; thus, in 1789, there were only 44 secular peers, independently of the princes of the blood, and the six originally created ecclesiastic peers; but the lower grades of nobility were so numerous that their numbers stood in the ratio of 1 to 150 of the entire population. Nevertheless, every grade of nobility exempted its holder from the payment of the ordinary land-tax, or *taille*, from the charge of maintaining the public roads (*corvée*), from military conscription, from receiving billets of soldiers, &c. The nobles paid the *capitation* tax, but in a very unequal proportion, although the landed property was vested almost entirely in their hands. They, in fact (together with the clergy), monopolized the principal share of the national revenues, and left to the lower classes the burden of labor and of paying the taxes. At the outbreak of the Revolution, the French nobility were sunk in profligacy, and fallen to the lowest stage of demoralization.

The clergy kept pace with the nobles in general depravity, and while their aggregate revenues amounted, according to Necker, to 130,000,000 of livres, and their landed property stood in the relation of 1 to 5½ of that of all other proprietors, their contributions towards the maintenance of the state were inadequate and irregular. The open profligacy and excesses of many of the higher members of the hierarchy, moreover, brought the whole order into disrepute. Francis I. had wrung from the church a tithe, known as the *décime pascaline*, and every five years the clergy were expected to present their so-called *dons gratuits ordinaires*, of from 15 to 18 million of livres; while on occasions of need they from time to time made extraordinary *dons gratuits*, which, however, were usually repaid at long intervals. The *tiers état* were crushed by the weight of an unjust taxation, which was rendered more obnoxious by the system of farming out some of the taxes. The most tyrannical of these was the tax on salt. The municipal institutions which had been permitted to flourish under some of the Valois princes in the middle ages, were almost entirely abolished, and the officers of towns, like those of the state and the courts of justice, were either hereditary or open to purchase. The *tiers état*, which included professional men, and all who were not either members of the noble or clerical orders, saw themselves utterly excluded from all participation in the privileges and duties of free citizens, at the very time when the extensive circulation of the writings of the philosophers of the 18th c., as Voltaire, Malesherbes, Rousseau, and Montesquieu, had habituated men's minds to the discussion of questions of political independence, equal rights, and universal freedom.

The resistance made by Louis and his advisers to the reasonable demands of the Deputies on the 17th June 1789, led to the constitution of the National Assembly—a measure which was followed, on the 23d of June, by a declaration of the inviolability of the members. The king retaliated by ordering a large body of troops under arms, dissolved his ministry, and banished Necker, whom he had shortly before recalled under the pressure of public opinion. The consequence was the outbreak of insurrectionary movements at Paris, where blood was shed on the 12th July. On the following day, the national guard was convoked; and on the 14th, the people took possession of the Bastille. The provinces repeated the acts of Paris, and everywhere national guards and revolutionary municipal councils were called together. On the 4th of August, feudal and manorial rights were abrogated by the National Assembly, which gave expression to a solemn declaration of the equality of human rights. The royal princes and all the nobles who could escape sought safety in flight. The royal family having attempted in vain to follow their example, tried to conciliate the people by the feigned assumption of republican sentiments; but on the 5th October, the rabble, followed by numbers of the national guard, attacked Versailles, and compelled the king and his family to remove to Paris, whither the Assembly also moved. The next two years witnessed the solemn inauguration and the subsequent retraction of various constitutional schemes; the princes of the blood and the ancient noblesse raised corps of émigrés in different parts of the country, but their efforts could not arrest the spread of republicanism.

The king alternately made concessions to the republicans, and cherished schemes for escaping from their surveillance, but each month added to his humiliations and to the audacity of those surrounding him. A war with Austria was begun in April 1792; and the defeat of the French was visited on Louis, who was con-

fined in August with his family in the Temple. The advance of the Prussians into Champagne threw Paris into the wildest excitement. The National Assembly dissolved itself in September. In December, the king was brought to trial, and called upon to answer for repeated acts of treason against the republic. On the 20th January 1793, sentence of death was passed upon him; and on the following day he was beheaded. Revolts burst out in every part of France. England, Holland, Spain, Naples, and the German States combined together against the republic. Christianity was now formerly deposed, and the sacredness of the republic and the worship of reason solemnized. Marie Antoinette, widowed queen was guillotined; the dauphin and his surviving relatives suffered every indignity that malignity could devise. A reign of blood and terror succeeded. Danton and Robespierre, after having condemned countless numbers to the guillotine, suffered each in turn a similar fate. After the destruction of the Terrorists, a reaction was gradually established; the people were wearied of bloodshed, and anxious for peace and order at any cost. The brilliant exploits of the young general, Napoleon Bonaparte, in Italy, turned men's thoughts to other channels. In 1795, a general amnesty was declared, peace was concluded with Prussia and Spain, and the war was carried on with redoubled vigor against Austria. The Revolution had reached a turning-point. A Directory was formed to administer the government, which was now conducted in a spirit of order and conciliation. In 1797, Bonaparte and his brother-commanders were omnipotent in Italy. Austria was compelled to give up Belgium, accede to peace on any terms, and recognize the Cisalpine Republic. The glory of the French arms was re-established abroad, but at home the nation were still suffering from the shock of the Revolution. The Directory repudiated two-thirds of the national debt, and thus almost ruined the commerce and credit of France. Under the pretext of attacking England, a fleet of 400 ships and an army of 36,000 picked men were equipped; their destination proved, however, to be Egypt. Whither the Directory sent Bonaparte; but the young general resigning the command to Kleber, landed in E. in 1799, and at once succeeded in supplanting the Directory, and securing his own nomination as Consul, conjointly with Siéyes and Roger Ducos. In 1800, a new constitution was promulgated, which although, in appearance purely constitutional, in reality vested the whole executive power in Bonaparte, who showed consummate skill in re-organizing the government, to which he imparted a systematic efficiency and a spirit of centralization, that secured a thoroughly practical administration.

Having resumed his military duties, he marched an army over the Alps, attacked the Austrians unawares, and decided the fate of Italy by his victory at Marengo. In 1801, the peace of Lunéville was concluded, and the boundaries of F. were extended to the Rhine. England was the only country which refused to recognize the legality of the various Italian and German conquests of F.; and with the exception of a brief period of peace, this country remained the implacable foe of Bonaparte from the days of the Consulate to his defeat at Waterloo. Every period of respite from war was employed by the First Consul in reinstating trade and industry, and in obliterating both in private and public life the stains left by the Reign of Terror. In 1804, on an appeal by universal suffrage to the nation, Bonaparte was proclaimed emperor. The pope came to Paris to crown him and his wife Josephine; a new nobility was rapidly created, and the relatives and favorites of the emperor received vanquished kingdoms and principalities at his hands. For a time, Napoleon's influence with the weakened powers of the continent succeeded in maintaining an injurious system of blockade against England; and, except in the Peninsula, his arms were everywhere victorious. By his marriage with the Archduchess Maria Louisa, daughter of the Emperor of Germany, Napoleon seemed to have given to his throne the prestige of birth, which alone it had lacked. He now availed himself of the freedom afforded by the peace with Austria to expand the material prosperity of the country, by encouraging trade, constructing roads, bridges, and canals in every part of the empire, and by consolidating his government, and organizing a complete code of laws and a systematic mode of administering them. But this period was the poorest in respect to the literary and scientific development of the nation, who were too much trammelled by police supervision and military discipline to exercise freedom of thought and intellect, and this interval of comparative repose was soon interrupted by the ambitious designs of Napoleon on Germany, which led to a declaration of war against Russia in 1812. From this time to his final defeat in 1815, the emperor rapidly receded from the lofty station he had won for himself. The disastrous Russian campaign, in which his noble army was lost amid the rigors of a northern winter, was soon followed by the falling away of his allies and feudatories. Napoleon himself was still victorious wherever he appeared in person, but his generals were beaten in numerous engagements; and the great defeat of Leipsic compelled the French to retreat beyond the Rhine. The Swedes brought reinforcements to swell the ranks of his enemies on the

east frontier, while the English pressed on from the west; the senate, and his ministry betrayed his cause, and the allies threw themselves on Paris, which, in the absence of the emperor, capitulated after a short resistance, March 30, 1814.

Napoleon now abdicated in favor of his young son, and retired to the island of Elba, the sovereignty of which had been granted to him. His wife and son removed to Vienna; his family were declared to have forfeited the throne; F. was reduced to her former limits, and the provinces she had acquired were restored to their national rulers. On the 3d May, Louis XVIII. (the brother of Louis XVI.) made his entry into Paris. The conduct of the Bourbons did not conciliate the nation; they returned loaded with debts, and surrounded by the old nobility and clergy, who had not renounced their former privileges, and who looked upon the generation of Frenchmen who had arisen during their absence as their natural enemies. A narrow spirit influenced the weak policy of the king, which led to the establishment of a strict censorship, the extension of the powers of the police, and the persecution of all the adherents of the Empire; while the lower classes and the army, who were alike sensible of the humiliating reaction which had followed the former excitement of war and conquest, were treated with an indifference, and even contempt, by the returned emigrés, to which they were wholly unaccustomed. On the 1st March 1815, Napoleon left Elba, and landed in France. Crowds followed him; the soldiers flocked around his standard; the Bourbons fled, and he took possession of their lately deserted palaces. The news of his landing spread terror through Europe; and on the 25th March, a treaty of alliance was signed at Vienna between Austria, Russia, Prussia, and England, and preparations at once made to put down the movement in his favor, and restore the Bourbon dynasty. At first, the old *prestige* of success seemed to attend Napoleon; but on the 18th June, he was thoroughly defeated at Waterloo; and having placed himself under the safeguard of the English, he was sent to the island of St. Helena, in conformity with the generally acknowledged sentiment, that it was necessary to the peace of Europe to remove him finally and definitely from the scene of his former power. The second restoration gave occasion to many pledges of a more liberal policy on the part of Louis, but few of them were fulfilled, and a general and sullen discontent reigned among the people, who were again deprived of all voice in the administration, or in the election to offices, and were harassed by the petty tyranny of the priests, who were the favorite advisers of the crown. In 1821, Napoleon breathed his last at St. Helena; and in 1824, Louis XVIII. died without direct heirs, and his brother, the Duc d'Angoulême, succeeded as Charles X. The same ministerial incapacity, want of good faith, general discontent, and excessive priestly influence characterized this reign, which was abruptly brought to a close by the revolution of 1830, and the election to the throne of Louis Philippe, Duke of Orleans, as king, by the will of the people. Legitimist insurrections disturbed the nation; one *émeute* succeeded another; attempts upon the king's life were frequent; but the progress in material prosperity made the government popular with the *bourgeoisie*, or middle classes, and for a time it held its ground.

The warlike propensities of the nation found an outlet in the war in Algeria (q. v.) with Abd-el-Kader. But the determined resistance of the king to the growing desire for electoral reform, led at last to open insurrection in Paris; and Louis Philippe having abdicated (February 24, 1848), a Republic was proclaimed under a provisional government. An insurrection of the Red Republicans in Paris (June 1848), was only put down after great slaughter. Louis Napoleon (q. v.) was elected President of the Republic in December 1848; but by the famous *coup d'état* of December 2, 1851, he violently set aside the constitution, and assumed dictatorial powers; and a year after (2d December 1852), was raised, by the almost unanimous voice of the nation, to the dignity of Emperor as Napoleon III. His rule was one of complete absolutism, under which, however, France made great advances in the development of her natural resources, and in manufactures. Assuming the character of an adjuster of the wrongs of nations, Napoleon proclaimed himself a mediator in the Danish and Austro-Prussian wars, and the defender of the Italians against Austria, of the Pope against the people of Italy, and of the Mexicans against the government of the United States of America. By his help the Italians were relieved from the Austrian yoke, and the pope was left master of Rome; but in Mexico his intervention only led to greater bloodshed, and ended ignominiously for the glory of F., and fatally for the cause and life of his protégé, the Austrian Prince Maximilian (q. v.). Attempts to gain a Prussian alliance ended in humiliating repulses. Although the brilliant success of the Paris Exhibition of 1867 seemed to afford evidence of the personal and national consideration in which the emperor was held, his political credit had already then lost its importance. At home, the great financial embarrassments of his government were arousing the discontent of the people; and to avert the growing disaffection, Napoleon offered (1869) to adopt a constitu-

tional form of government, and to make some concessions in regard to freedom of the press. It was soon found that the responsibility of the ministry was fictitious; and that the emperor availed himself of its protection to cloak his own acts of personal government. The result of the appeal made to the nation in 1870, on the plea of securing their sanction for his policy, was not what he had anticipated; and the 50,000 dissentient votes given by the troops in this plébiscite, revealed a hitherto unsuspected source of danger. Confident in the efficiency of the army, and anxious to rekindle its ardor, he availed himself of a pretext to declare war against Prussia. The course of events in the short but terrible Franco-German conflict of 1870—1871 electrified Europe by its unexpected character, revealing at once the solidity of Prussian strength and the hollowness of imperial power in F. Within a fortnight of the emperor's appearance at the head of his troops at Metz, July 28, 1870, the strength of the French army was annihilated, Alsace and Lorraine were occupied by Germans, and the Chamber of Deputies in Paris was clamoring for his abdication.

On September 2, Napoleon, with his army of 90,000 men, surrendered at Sedan, and on the 4th, Paris was in rebellion, the senate dissolved, the Empress Regent a fugitive on her way to England, and F. proclaimed a Republic amid tumultuous excitement. Before the close of September, Strasburg, one of the last hopes of F., had capitulated, and Paris was completely invested by German troops; and on 5th October, the Prussian king had taken up his headquarters at Versailles. The fall of Metz, with 200,000 men, completed the disasters of the year. In January 1871, the united efforts of the different branches of the Provisional Government of Defence, respectively installed at Paris and Tours, succeeded in bringing about an armistice, after the besieged Parisians had for four months been hourly exposed to the fire of the enemy, cut off from all communication with the outer world except by balloons and carrier-pigeons, and finally threatened by famine. With the concurrence of Prussia, the French nation now proceeded, by a general election of representatives, to provide for the exigencies of the country. The First National Assembly of the French Republic met at Bordeaux in February. After receiving from the Provisional Government of Defence the resignation of the powers confided to them in September 1870, the Assembly undertook to organize the Republican Government, and nominated M. Thiers chief of the executive power of the state, with the title of President of the French Republic, but with the condition of responsibility to the National Assembly. On the 1st of March the preliminaries of peace were finally ratified at Bordeaux, the chief conditions being that the province of Alsace (except Belfort) and part of Lorraine, including Metz, should be ceded to the German empire, and that F. should pay a war indemnity of 5000 millions of francs, and continue to be occupied by German troops till the money was all paid. This enormous obligation was discharged in September 1873, and during the same month, F., after an occupation of three years, was finally relieved from the presence of foreign troops. In the spring of 1871, the peace of F. was seriously threatened by a successful outbreak at Paris on the part of the Communists (q. v.), who after great bloodshed and grievous damage to public and private property, were quelled by the regular army, which had sided with the government, and on 20th of May order was restored in Paris. Since then, F. has been successfully trying to obliterate some of the numerous misfortunes resulting from the war, and commerce and national prosperity have very rapidly revived. The ex-emperor Napoleon died in 1872, at Chislehurst, where he had resided with his family since his liberation in March 1871. In 1873 M. Thiers resigned the office of President of the French Republic, and was succeeded by Marshal MacMahon, who soon had his presidential powers confirmed to him for a period of seven years, generally known as the Septennate. The ministry of the Duc de Broglie was composed mainly of Legitimists, Orleanists, and Bonapartists, and in its time ultramontanism and Bonapartism made progress. The fusion of the Orleanists and Legitimists, though earnestly attempted, was completely foiled by the obstinacy of the Duc de Chambord.

Several ministries succeeded that of De Broglie, and there were fears of a *coup d'état* on the part of the president. But the elections of 1877 returned a large republican majority to the Chamber of Deputies; and MacMahon, yielding to the national will, summoned M. Dufaure, who chose a thoroughly republican ministry. In 1879, the Senate also became predominantly republican. Reactionary prefects were removed; and, on the whole, the republican form of government was greatly consolidated during MacMahon's tenure of office, and continued to secure more and more the confidence of the French people. The national vigor and prosperity were manifested in a successful International Exhibition at Paris in 1878. Early in 1879, MacMahon, disapproving of certain military changes, resigned office, and M. Grévy (q. v.) became president. There have been many changes of ministry (M. Gambetta, long known to be the most important statesman in France, formed a ministry in November 1881, and resigned in January

1882), but the current of policy has been steadily republican. An amnesty was granted to the Communist prisoners. At the instance of M. Ferry, a decree was issued by which Jesuit schools were closed; all unrecognized religious orders declining to submit to the conditions necessary for state sanction, were dissolved; and some 7400 inhabitants were thus expelled from 384 monasteries. Much controversy turned on the proposal, supported by M. Gambetta, to make the department the electoral unit of area (introducing *scrutin de liste*), instead of the *arrondissement* (with *scrutin d'arrondissement*) as heretofore. Nominally to punish certain Tunisian Kroumir tribes for incursions into Algerian territory, France sent an expedition to Tunis in 1881, and compelled the Bey to sign a treaty by which Tunis became virtually a French protectorate (see TUNIS). The native tribes continued to offer much armed opposition to the French terms, and prolonged campaigns in the interior of the country were rendered necessary. At the same time, some of the Algerian tribes rose in insurrection.

FRANCE, ISLE OF. See MAURITIUS.

FRANCESCO DI PAULA, founder of the order of the *Minims*, was born in 1416 at Paula or Paolo, a village of Calabria. At the age of 12, he was the inmate of a Franciscan convent; and at 14 he retired to a cave, where he inflicted on himself every species of self-mortification. The fame of his piety having attracted to his cell several emulators of his austere life, he received permission to erect a convent, and the new community received from Pope Sixtus IV. the title of the Hermits of St. Francis. To the usual conventual vows, F. added one of the most rigorous abstinence—flesh, eggs, and milk being strictly forbidden the entire year, except in illness. Popular report having attributed to F. several wonderful cures, Louis XI. of France, being ill, summoned him to his presence. F. was received with the highest honor, and attended the king on his death-bed. Charles VIII. and Louis XII. induced him to settle in France, and built him convents at Plessis-le-Tour and Amboise. F. died in 1507, and was canonized in 1519.

FRANCHE COMTÉ, an old province in the east of France, in the basin of the Rhone, comprised what now forms the departments of Doubs, Haute-Saône, and Jura, and had for its capital Besançon.

FRANCHISE, in English law, is a royal privilege, or branch of the crown's prerogative, subsisting in the hands of the subject. Franchise properly means freedom, and by an easy transition, the privileges of the freeman; whence it came to signify the privileges just defined. Being derived from the crown, franchises must arise from royal grant, or in some cases may be held by prescription, which presupposes a grant. The subjects of franchise being the peculiar property of the crown, correspond with what in Scotland are called regalia. Gifts of waifs, estrays, wrecks, treasure-trove, royal fish, and forfeitures, are franchises; so are the rights of forest, chase, park, warren, and fishery. A county palatine (see PALATINE) is the highest species of franchise. So the crown may create a liberty or bailiwick independent of the sheriff of the county. It is likewise a franchise for a number of persons to be incorporated, with a power to do corporate acts; and each member of such corporation is also said to have a franchise. The right to hold a fair or market, or to establish a ferry and to levy tolls therein, is also a franchise. Franchises may be extinguished by re-union with the crown, or may be lost by *misuser* or by *non-user*.

FRANCHISE, in its political acceptance, is the right of the individual to exercise a certain limited portion of the general sovereignty of the state. A franchise in this sense is possible only in a free state—in a state in which the governed, as a whole, are identical with the governors. Where legislation is effected by the votes of the people themselves, as it was in the small states of antiquity, the franchise is exercised by each individual directly. Where representation has been introduced, the franchise is the right which the citizen has of voting for his representative. The extent or value which ought to belong to the franchise will be measured by the amount of the sovereignty which it expresses. But this sovereignty finds forms of actual expression, in the amount of power and influence which is conceded to the individual by the society of which he is a part. A theoretically just franchise, then, would be one which corresponded accurately to the social position of each individual. An approximation is all that is possible in dealing with the mass, and one of the questions which is at present most keenly discussed amongst speculative politicians is, by what test shall this approximate estimate of social value be brought most nearly to the truth. Mill proposed intelligence, as indicated by instruction, as the sole measure of individual sovereignty, and, consequently, as the basis of the franchise. Others have proposed wealth; whilst by a third class of speculators it is contended that, in the case of each individual, there are various elements of social importance which must be taken into account in determining the political value which is his due.

By most recent writers on the theory of government, however, the idea of all citizens being entitled to an equal suffrage, however great might be the disparity of intelligence, wealth, manhood, and other elements which go to make up social importance, is repudiated as a scientific absurdity. See Mill's work on Representative Government; also PARLIAMENT.

FRANCIA, DR. JOSE GASPAR RODRIGUEZ, Dictator of Paraguay, was the son of a small landed proprietor, of French or Portuguese origin, and was born near the town of Asuncion in 1757 or 1758. He was intended for the church, studied at the university of Cordova de Tucuman, where he took his degree as a doctor of divinity or of canon law, and was for some time a theological professor. Subsequently he adopted the profession of law, to the practice of which he continued to devote himself for a period of thirty years, gaining much reputation for learning, skill, honesty, and independence of character. When he had attained the age of fifty-two or fifty-three, the revolution which shattered the Spanish yoke in South America broke out in Buenos Ayres. Paraguay at first offered active opposition to the revolutionists, but ultimately sought to obtain independence for itself. F. took a leading part in the movement, and was made secretary of the independent junta set up, but he soon resigned his post. The conviction, however, being strong in the public mind that F. alone could properly direct the affairs of the new republic, he was, in 1813, appointed joint-consul along with General Yegros. The latter, however, was a man apparently without much intellect or energy, and F. was really sole ruler from the first. In 1814, he was appointed dictator for three years, at the expiry of which time the dictatorship was given him for life; and the absolute control so conferred he exercised until his death in 1840. Under F., the condition of Paraguay rapidly improved, and the system of non-intercourse, political or commercial, with other nations, which he enforced, however much it may seem to prove him devoid of administrative sagacity, was undoubtedly attended with good results to his country. So strict were the regulations against foreign intercourse, that ingress to, or egress from, Paraguay was next to impossible; and F.'s treatment of some foreigners who did get in (among others the famous savant Bonpland), and of others who were prevented entering, savored of harshness, and even barbarism. Yet his administrative talent was of a high order. He improved agriculture, making two crops of corn grow where only one had grown before. He introduced schools, promoted education, repressed superstition, and enforced strict justice between man and man in his law-courts. His death was regretted by the people as a public calamity—the best proof that he was no vulgar tyrant. See Rengger and Longchamp's *Assai Historique*, &c. (Paris, 1827); *Francia's Reign of Terror* (London, 1839), by J. P. and W. P. Robertson, two young Scotchmen whom F. turned out of the country; and T. Carlyle's essay in the *Edinburgh Review* (1843).

FRANCIS, OF ASSISI, founder of the Franciscan order, and a saint of the Roman Catholic Church, was one of the most extraordinary men of his age, and merits a detailed notice, as illustrating in his career all the most remarkable characteristics of the religious life of the middle age. He was born in 1182, of the family called Bernardini, at Assisi, where his father was engaged in trade. His baptismal name was John; but from his familiarity with the Romance, or language of the troubadours, in his youth, he acquired the name of *Il Francesco* ('The little Frenchman'). In his early years, he was remarkable for his love of gaiety and ostentatious prodigality; but even then his bounty to the poor was one of the largest sources of his wastefulness. He engaged eagerly in exercises of chivalry and of arms; and in one of the petty feuds of the time, he was taken prisoner, and detained for a year in captivity at Perugia. An illness which he there contracted turned his thoughts from earth; and although he again engaged in military pursuits, a second illness at Spoleto decided his career for life. He now resolved to fulfil literally the counsels of the gospel, and he especially devoted himself to poverty, which, in the mystic language thenceforth familiar to him, he designated as 'his bride.' Under an impulse which he received while listening to a sermon, he took a vow never to refuse alms to a beggar. He made a pilgrimage to the tomb of St. Peter at Rome, and there offered to God all that he possessed on earth. On his return to Assisi, he exchanged his clothes with a poor mendicant; and disregarding all remonstrance and ridicule, he ever afterwards continued to wear the meanest attire. He gave to a priest who was rebuilding a ruined church the price of his horse, which he sold for the purpose, and even sought to appropriate to the same use the moneys of his father, which, however, the priest refused to accept. To avoid his father's anger, he took refuge in a cave, in which he spent a month in solitary prayer, and from which he returned more than ever confirmed in his enthusiasm. His father having in vain confined him in a dark room of his own house, cited him before the magistrates, and, on F.'s declining all civil jurisdiction in such a case, before the bishop, in order to compel

him to renounce his inheritance. F. abandoned all, even to the very clothes he wore, and then declared that 'till now he had been the son of Bernardini, but that henceforth he had but one Father, him that is in heaven.' Thenceforth, no humiliation was too low for F.; he begged at the gates of monasteries; he discharged the most menial offices; he served the lepers in the hospital at Gubbio in their most revolting necessities, and with the most tender assiduity. He worked with his own hands at the building of the church of St. Damian, and at that of Sta. Maria degli Angeli, which he afterwards called his 'Portiuncula,' or 'little inheritance,' and as the last act of self-spoilation, and the final acceptance of the gift of poverty, he threw aside his wallet, his staff, and his shoes, and arrayed himself in a single brown tunic, of coarse woollen cloth, girt with hempen cord. This was in his 26th year, in 1208.

His enthusiasm by degrees excited emulation. Two of his fellow-townsmen, Bernard Quintavalle and Peter Cattano, were his first associates. They were followed, although slowly, by others; and it was not till 1210, that, his brotherhood having now increased to eleven in number, he drew up for them a rule, selected in the true spirit of religious enthusiasm, by thrice opening at random the gospels upon the altar, and taking the passages thus indicated as the basis of the young institute. (Milman's *Latin Christianity*, iv. 264.) The new brethren repaired to Rome, where their rule was approved (though at first only *visu voce*) by Pope Innocent III. in 1210.

The two following years were spent by the brotherhood in preaching and exhorting the people through the rural districts of their native and the adjoining provinces; and F. himself returned to Assisi in 1212, at which time he finally settled the simple constitution of his order, the church of Sta. Maria degli Angeli being assigned to them as their home. In common with the older forms of monastic life, the Franciscan institute is founded on the three vows of chastity, poverty, and obedience; but of these the second was, in the eyes of F., the first in importance and in spiritual efficacy. In other orders, the practice of poverty consisted in the mere negation of riches. With F., it was an active and positive principle. In other orders, although the individuals could not possess, it was lawful for the community to hold property in common. F. repudiated all idea of property, alike for his order and for its members; he even disclaimed for them the property in those things which they retained for personal use—the clothes which they wore, the cord with which they were girded, the very breviary from which they chanted the divine office. The very impossibility, to human seeming, of these vows, was their strength. Numbers crowded to the standard of Francis. He told them off in parties to different provinces of Italy. Five of the brotherhood repaired to Morocco to preach to the Moors, and, as the first martyrs of the order, fell victims to their holy daring. Success removed all the hesitation with which the institute at first was regarded, and in 1216, the order was solemnly approved by Pope Innocent. From this date it increased with extraordinary rapidity. At the first general assembly, held in 1219, 5000 members were present; 500 more were claimants for admission. F. himself inaugurated the future missionary character of his brotherhood by going (1223) to the East, and preaching the gospel in the presence of the sultan himself; but the only fruit of his mission was a promise from the sultan of more indulgent treatment for the Christian captives, and, for the Franciscan order, the privilege which they have since enjoyed, as guardians of the Church of the Holy Sepulchre. It is after his return to Italy that his biographers place the celebrated legend, which, to friends or to enemies, has so long been a subject of veneration or of ridicule—his receiving, while in an ecstasy of prayer, the marks (*stigmata*) upon his own person of the wounds of our Divine Redeemer.

The scene of this event is laid on Monte Alverno, a place still sacred in the traditions of the order; and the date is September 17, 1224. Two years later, St. F. died, October 4, 1226. On the approach of his last hour, he requested that he should be carried upon a bier to the church, where he had himself placed on the bare ground, thus realizing in his own death the most literal extreme of the doctrine which he had made in life the basis of his system. He was canonized by Pope Gregory IX. in 1228.

The works of St. F. (folio, Pedeponti, 1739) consists of letters, sermons, ascetic treatises, proverbs, moral apothegms, and hymns. The latter are among the earliest metrical specimens of the Italian language. They are exceedingly simple, and full of the tenderest expressions of the Love of God. His prose is often more poetical than his poetry itself, abounding in allegory and poetical personification. Few writers have ever turned the love and admiration of external nature to a purpose so beautifully devotional. 'Of all the saints,' says Dean Milman, 'St. Francis was the most blameless and gentle.' No saint, it may be added, has been the subject of more exaggerated panegyric from the writers of his order; and one of the works in his praise—a parallel between St. F. and our Divine Redeemer—is disowned by the Roman Catholic community as a most reprehensible exaggeration, the fruit of an affectionate,

but most misdirected zeal for the memory of the founder of the Franciscan order.

FRANCIS, SIR PHILIP, son of the Rev. Dr. Philip Francis, author of a well-known translation of Horace, was born at Dublin, October 22, 1740, and educated at St. Paul's School, London, where he had for a school-fellow Henry S. Woodfall, afterwards the printer of the *Public Advertiser*, and the publisher of the *Letters of Junius*. In 1756, he obtained a place in the office of Mr. Fox, then secretary of state, which he retained under his successor Mr. Pitt. In 1760, he became secretary to the Earl of Kinnoul, who had been appointed British ambassador to Portugal; and on his return to England in 1763, he received an appointment in the War-office. Ten years later, he was sent out to India, as a member of the council for the government of Bengal, with a salary of £10,000. Here he came into collision with the governor-general, Warren Hastings, and so far did the quarrel proceed, that a duel was the consequence, in which F. was severely wounded. In December 1780, he resigned his situation, and returning to England, entered parliament for the borough of Yarmouth, in the Isle of Wight, in 1784. He never obtained a reputation as an orator, but his great abilities and extensive information always commanded the respect and attention of the House.

The prosecution of Hastings, begun in 1786, was hailed by him with malignant joy, and it must be confessed that he displayed a most ungenerous alacrity and activity in furthering the designs of the committee of impeachment. In his political opinions, F. was a decided and consistent Whig, at a time when Whiggism meant very much the same as the Radicalism of a later period. He exulted at the success of the French Revolution, was an active member of the association of 'Friends of the People,' and ably supported the efforts of Fox and Grey for a reform in the representation of the nation. He withdrew from parliament in 1807, and died December 22, 1818. F. wrote upwards of twenty political pamphlets. He has also been considered by many to have the best claim to the authorship of the *Letters of Junius* (q. v.).

FRANCIS I., king of France, son of Charles, Comte d'Angoulême, was born at Cognac, September 12, 1494, and in his youth manifested an ardent love for literature, especially for the romances of chivalry, whence, probably, he drew his brilliant but erroneous views of a kingly character. At the age of twenty, he married Claude, daughter of Louis XII., and succeeded his father-in-law, January 1, 1515. His first act after mounting the throne, was to set about the reconquest of Milan, which had been wrested from his predecessor two years before, and at the head of 40,000 men, among whom were such great warriors as the Constable Bourbon, Bayard, Lautrec, and Trivulzio, F. crossed the Alps, and attacked the Swiss allies of the Milanese at Marignano, ten miles from Milan. Here a sanguinary battle, afterwards called the 'battle of the giants,' ensued (13th September 1515), in which F. obtained a complete victory—the Swiss losing 12,000 men. In accordance with his chivalrous propensities, F. accepted knighthood on the field from the renowned Bayard. After some further successes, F. returned to Paris in the month of February 1516. On the death of Maximilian, emperor of Germany, in January 1519, F. and Charles of Spain became rival candidates for the imperial crown. The election of the latter excited the anger of F., who immediately prepared for war, and endeavored to secure the alliance of Henry VIII. of England. An interview took place in 1520 between the two monarchs on the famous *field of the cloth of gold*, between Guines and Ardres, but it led to no result, and shortly after, Henry formed an alliance with the pope and the emperor against Francis. The papal troops drove the French out of Italy; and the soldiers of Henry and the emperor invaded France on the north, while, to complete his perplexities, the Constable Bourbon, who was discovered to be conspiring against his sovereign, fled to Charles, who gladly accepted the sword of the renegade warrior. F. gallantly faced the dangers that now threatened his kingdom. A large army was sent to Italy under the command of Bonnivet, who, however, proved incapable, and was forced to retreat across the Alps. In the course of this retreat, Bayard lost his life. The imperialists now advanced into Provence, but, on the approach of the French king, withdrew into Italy, whither they were followed by F., who overran Lombardy, but was totally defeated and taken prisoner at the battle of Pavia, 24th February 1525.

Charles carried his captive to Madrid, and only granted him his liberty on the hardest conditions. F. had to renounce the suzerainty of Flanders and Artois, the duchy of Burgundy, and all his Italian possessions and prerogatives, to promise the restoration of Bourbon to his former dignities, and to surrender his two sons

as hostages. He obtained his freedom, March 17, 1526; but regarding the conduct of Charles as utterly base, his first act, on his return to his dominions, was a refusal to fulfil the pledges he had given. Pope Clement VII. absolved him from his oath; England, Rome, Venice, Florence, and Genoa—all of whom were growing alarmed at the immense power of Charles—withdrew from the imperial alliance, and sided with his antagonist. The war in Italy now recommenced. On the 5th May 1527, Bourbon's 'black banditti' stormed and sacked the 'Eternal City,' and captured the pope. F. now sent troops into Naples, which, after a series of brilliant successes, were almost wholly cut off by disease, mainly through the negligence of the king, who failed to supply them with the means of subsistence. About the same time, F. sent a challenge to Charles to decide their quarrel by single combat. The challenge was accepted, but the duel never came off. At last, a peace was concluded at Combray, in July 1529, much to the advantage of the Spaniards. In 1534, however, war broke out between F. and the Duke of Milan; and in the following year the former overran Savoy, to which he laid claim by the absurd pretensions. The conduct of Charles at this period was marked by the greatest moderation, but he was ultimately involved in hostilities with his inveterate opponent. Little definite result ensued, but the war was marked by a circumstance regarded as horrible in those days—viz., an alliance between Christians and Turks. F. formally entered into a league with the Sultan Soliman, who went so far as to land troops in the south of Italy, but the French king shrunk from a practical co-operation with the arch-enemy of Christendom. By the efforts of Pope Paul III., a treaty was concluded for ten years at Nice between Charles and F., 18th June 1538. In point of fact, however, peace lasted only four years, and in 1542, F., insatiable of glory, launched five different armies against the emperor. The battle of Cerissoles, 14th April 1544, in which the French were completely victorious, partially wiped out the dishonor of the defeat at Pavia, but a second alliance of F. with the Turks renewed the indignation of Christendom. Charles, and Henry king of England, marched upon Paris, and F. was compelled to make peace at Crepy, 18th September 1544. His political rôle was now finished. He died at Rambouillet, March 31, 1547. It is not difficult to estimate the character of this monarch. Gay and voluptuous (it was the physical consequences of an amour which cost him his life), he was still capable of heroic impulses and acts of splendid generosity. But no amount of 'chivalry' could compensate for the lack of political sagacity; it could not even save him from deeds of cruelty. His persecution of the Vaudois and other 'heretics' has left a dark stain on his memory, which all his patronage of arts and letters will not efface. F. was himself a writer of verses; but these were so bad that even French critics pronounce them almost intolerable.

FRANCIS I. (STEPHEN), Emperor of Germany, born in 1708, was the eldest son of Leopold, Duke of Lorraine. On the death of his father, in 1729, F. succeeded him in the dukedom, which, in 1735, he ceded to Stanislaus Leszcynski, father-in-law of Louis XV., to revert after his death to the crown of France. In lieu of Lorraine, he obtained the grand duchy of Tuscany, whose native rulers, the Medicean family, were about to die out. In 1736, he married Maria Theresa of Austria, the only daughter and heiress of the Emperor Charles VI. In 1740, Charles died, and Maria Theresa succeeded him; she made her husband co-regent with herself, but gave him little share in the administration. F. fought bravely for his wife's rights in the wars carried on against Frederick the Great. In 1745, he was elected to the once important dignity of Emperor of Germany, and crowned at Frankfurt. The famous Seven Years' War (1756—1763) now broke out between Austria and Prussia; but the cares which it imposed fell mainly upon his leonine consort, Maria Theresa. F. died at Innsprück, 18th August 1765. His son Joseph succeeded him in the imperial dignity, but Maria Theresa retained in her hands the sovereignty of the Austrian dominions till her death.

FRANCIS II., Emperor of Germany and I. of Austria, the eldest son of Leopold II. Grand Duke of Tuscany, and of Maria Louisa, daughter of Charles III., king of Spain, was born at Florence, in February 1768. In 1790, his father became Emperor of Austria by the death of his brother Joseph, but died only two years after, when the crown devolved upon Francis. The French Revolution was now exciting the alarm of the old European dynasties; F. concluded an alliance with Prussia against the new republic; and the armies of the allies marched to the frontiers of France, but soon recoiled before the fiery enthusiasm of the republican troops. In 1794, F. placed himself at the head of the army of the Netherlands, which, on the 26th of April, defeated the French at Cateau and Landrecy; and on the 22d of May, gained the bloody battle of Tournay; but on the whole the fortune of the war was against him; and the triumphs of young General Bonaparte in Italy forced him to conclude the treaty of Campo Formio (October 17, 1797). Only two years afterwards, however,

F., in alliance with Russia and England, again took up arms, and was at first successful; but the recall of the brave Russian general, Suwaroff, and the return of Bonaparte from the East, quickly altered the state of matters. The great victories won by Moreau at Hohenlinden, and by Bonaparte at Marengo, paralyzed the powers of Austria, and F. was compelled to sue for peace, which was obtained by the treaty of Lunéville in 1801, by which the whole of the left bank of the Rhine was ceded to France. In 1805, the aggressions of France once more excited the jealousy of Austria. F. entered into a new alliance with Russia; and the contest was renewed, but ended more disastrously than ever for the Austrians. The French victories of Ulm and Austerlitz, and the capture of Vienna, completely humiliated F., who, at the peace of Presburg (December 1805), was obliged to surrender the Venetian states and the Tyrol. The German empire was now dissolved, after lasting for 1000 years, and F. assumed the title of Emperor of Austria, King of Bohemia and Hungary.

In 1809, he recommenced the war with Napoleon, and obtained more success, or perhaps we should say, encountered less loss than on previous occasions. The tremendous battle of Aspern was a victory, though not a decisive one, and did much to restore the prestige of the Austrian arms. Still Napoleon again got possession of Vienna, and dictated terms of peace from the palace of Schönbrunn in October of the same year. In 1810 the French emperor married F.'s daughter, Maria Louisa. A permanently friendly alliance now seemed to be concluded between the two empires; and during the Russian campaign in 1812, the Austrians rendered the French some slight assistance. In 1813, Austria resumed its neutrality; but, after having exerted himself fruitlessly to mediate between France and Russia, F. suddenly joined the allies, helped to win the battle of Leipsic, and followed the Russians and Prussians to Paris in 1814. His subsequent career does not present any points of special importance. He labored honestly and indefatigably for the welfare of his subjects, encouraging the making of roads and canals, and the introduction of manufactures; but his horror of everything revolutionary, excited by his early recollections, and by the cruel death of his aunt Marie Antoinette, and kept alive by his long wars with France, had rendered him an absolutist in politics, and a lover of that system of centralization to which Austria continues to cling. F. died on the 2d of March 1835.

FRANCIS JOSEPH, the present Emperor of Austria, born 18th August 1830, is the eldest son of the Archduke Francis (son of the Emperor Francis I.), and Sophia, a princess of Bavaria. F. was taught to speak all the various languages of his heterogeneous dominions, and only the year before the Hungarian revolution addressed the Magyar nobles at Pesth in their own language—a circumstance which secured him a certain transient popularity. In 1848, he served under Radetzky in the Italian wars. The Emperor Ferdinand having, in the hour of his extremity, made certain constitutional promises to the nation, the archduchess, F.'s mother, who during the whole year had directed the schemes of the anti-revolutionary party, resolved that the fulfilment of these promises should be evaded by a change of sovereign. Ferdinand accordingly abdicated in favor of his nephew (2d December 1848), and F. assumed the government as Emperor of Austria, and King of Hungary and Bohemia. Hungary, however, which had lost all faith in the House of Hapsburg, rose in arms, and refused to accede to the change of succession; and Italy again tried the fortune of war. The progress of the struggle between F. and the constitutionalists of Hungary is described in the biographies of Kossuth, Bem, Dembinski, Batthyani, &c. Suffice it to say that Austria triumphed in Italy, and also in Hungary, through the alleged treachery of Görgei and the help of Russia. F. now devoted himself, with characteristic persistency, to the re-establishment of 'order,' that is to say, of despotism.

He dissolved the national guard, and took away the freedom of the press, and on January 1, 1852, abolished the constitution of his uncle, which had been a dead-letter from the beginning. In 1853 he nearly lost his life by assassination, and in the Crimean War forfeited the respect of all the belligerents by his indecisive attitude. The *concordat* of 1855, by which certain extraordinary privileges were conferred on the bishops of the Roman Catholic Church, was another step backwards. Meanwhile the dissatisfaction of Lombardy, Venice, and Hungary hourly increased. Sardinia encouraged the national feeling in Italy, and at last, in 1859, F. hurried thoughtlessly into a war with that kingdom, which ended in the cession of Lombardy. For the war with Denmark, see SLESVIG; for the war with Prussia, and the subsequent work of reconstructing the empire, see GERMANY. F. was crowned as king of Hungary at Pesth in 1867. He was present at the opening of the Suez Canal in 1869. See also AUSTRIA, HUNGARY.

FRANCISCANS, ORDER OF, also called MINORITES or LESSER BRETHREN, a religious order of the Roman Catholic Church, founded by St. Francis of Assisi. For an account of the estab-

lishment of the Franciscan order, and its earliest fortunes, see FRANCIS OF ASSISI. The subsequent progress of the order was equally wonderful. In less than half a century it reckoned no fewer than 33 'provinces,' the aggregate number of convents in which exceeded 8000, while the members fell little, if at all, short of 200,000. Some idea, indeed, of the extraordinary extension of this remarkable institute may be formed from the startling fact, that, in the dreadful plague of the Black Death in the following century, no fewer than 124,000 Franciscans fell victims to their zeal for the care of the sick, and for the spiritual ministrations to the dying! But this marvelous external progress was accompanied by serious internal controversies and divisions. In the original scheme of the institute, its great fundamental characteristic was poverty, which St. Francis proposed to render in his order not only more perfect theoretically, but more systematic in its practice, than it existed in any of the contemporary institutes. For the accomplishment of this design, the rule which he drew up contained a few brief and simple, but, understood literally, very effectual provisions; but the difficulty of their literal observance led, even in the life time of St. Francis, to an attempt in the general assembly of the order to introduce some important modifications and, though the authority of the founder was sufficient to prevent the adoption of these modifications during his lifetime, and although his last will contained a special clause prohibiting not merely all change of the rule, but even all interpretation of it, the attempt was renewed with still more determination under Brother Elias, his successor in the office of general of the order. The great subject of controversy was the nature and extent of the obligation of religious poverty, as vowed in the order. Francis desired that it should be understood in the most rigorous sense; and, in his scheme of poverty, neither the individual brethren nor the entire community could acquire or retain any right of property even in things of necessary use.

The rigorous party in the order sought to carry out this principle to the fullest extent; and they contended that it was unlawful for the order to acquire a right of property in houses, convents, or even churches; restricting their right in everything which they possessed to the simple use. Several successive popes sought, by explanatory decrees, to settle the dispute; and for a time a compromise was received, by which it was understood that the right of property in all *de facto* possessions of the order was vested in the see of Rome; but the foundations of the real controversy lay deeper than this. They regarded the practice, far more than the theory, of poverty; and the disputes to which they led eventuated not only in the formation of fresh off-shoots from the body in the new religious orders, to be named hereafter, but also in a large, and, for a time, formidable, secession from the church in the sect of the Fraticellians. See FRATICELLIANS.

The supreme government of the Franciscan order, which is commonly said to be the especial embodiment of the democratic element in the Roman Catholic Church, is vested in an elective general, who resides at Rome. The subordinate superiors are, first, the 'provincial,' who presides over all the brethren in a province; and secondly the 'guardian,' who is the head of a single convent or community. These officers are elected only for two years. The provincial alone has power to admit candidates, who are subjected to a probation of two years (see NOVITIATE); after which they are, if approved, permitted to take the vows of the order. Those of the members who are advanced to holy orders undergo a preparatory course of study, during which they are called 'scholars'; and if eventually promoted to the priesthood, they are styled 'fathers' of the order; the title of the other members being 'brother' or 'lay-brother.'

A very important feature, however, of the organization of the Franciscan, as it subsequently became of other orders, is the enrolment of non-conventual members, who continue to live in society without the obligation of celibacy; and in general, are only bound by the spirit, and not the letter, of the rule. They are called 'Tertiaries,' or members of the Third Order of St. Francis. See TERTIARY. It is impossible to overestimate the value of this institution in the disorganized social condition of that age. The Tertiaries were bound, as the very first condition of enrolment, to restore all ill-gotten goods; to be reconciled with all those with whom they had been at feud; to devote themselves to the practice of works of Christian charity; to avoid all unnecessary expenditure; to renounce the use of personal ornaments; to hear mass daily; to serve the sick and the hospitals; to instruct the ignorant; and, in a word, to practise as far as possible in the world the substance of the virtues of the cloister. The institute, in this form, undoubtedly exercised a powerful influence in medieval society. It counted members in every rank, from the throne to the cottage; and, although it was in some instances deformed by abuses and superstitious practices, the aggregate results were undoubtedly beneficial.

The Franciscan order has been the parent of many other religious institutes. The earliest of these is that of the 'Observantists,' or 'brethren of more strict observance.' The origin of this body

has been already indicated. The party in the order which contended for the more rigid observance of the rule, after a protracted struggle—in which disaffection to the church itself was often strongly exhibited—obtained a separate organization, which may be said to have been finally settled at the time of Leo X. The less rigid party, under the name of 'Conventuals,' obtained a distinct general, and an authorization for their mitigated observance of the rule. Their churches and convents admit greater richness of architecture and decoration; and they are at liberty to acquire and retain, in the name of the order, the property of these and similar possessions, all of which are renounced by the Observant Franciscans. The latter community comprises nearly 150 provinces. Their constitution is that of the original rule, as already explained. A second off-shoot of the Franciscan order, and in the same direction of rigorism, is that known as the 'Capuchins,' founded by Matteo di Basio, a Franciscan brother of the Observant rule, in the early part of the 16th century. Believing himself divinely called to revive the old spirit of his order, and learning that the modern habit of the brethren was different from that of St. Francis, he began with externals, and procured for himself, and obtained the papal permission to introduce (1528) the peculiar habit, with a pointed hood or cowl (capute), from which the name of the reformed order is derived. Along with this habit, however, Matteo adopted a very rigorous and mortified course of life, in which he was joined by others of the brethren; and the reform spread so rapidly among the community, that in the year 1536 a general chapter of the new congregation was held. They were subject, however, to the jurisdiction of the general of the Franciscan order. One of the first generals of the new reform was Bernardino Ochino, afterwards notable by his defection to Calvinism. After the Council of Trent, the Capuchins multiplied rapidly, though they were not introduced in France till the end of that century. A similar reform, to which the name of 'Recollets' was given (introduced in Spain by John de Guadalupe, in 1500), was approved by Clement VII. in 1532; and many of the new brethren were among the first Spanish missionaries to the New World. A further development of the rigoristic spirit is the congregation of 'Discalced' or 'Barefooted' (q. v.) Franciscans. The author of this reform was a Spanish Capuchin, Peter of Alcantara. In his capacity of provincial of Estremadura, Peter introduced many reforms; and in 1555 obtained the approval of Pope Julius III. for a new rule, which was afterwards confirmed by Pius IV.

The notice of the Franciscan institute would be incomplete without the mention of the several orders of nuns; as those of St. Clare, the Capuchin nuns, the Urbanist nuns, &c., which formed part of the same general organization. None of these, however, calls for any detailed explanation, or presents any very characteristic features.

The Franciscan order, in these several branches, has at all times maintained its popularity in the Roman Catholic Church. When Helyot, in the beginning of the 18th c., published his great *History of Religious Orders*, the Franciscan order numbered nearly 120,000 friars, distributed over above 7000 convents, and nearly 30,000 nuns, occupying about 900 convents. Since the French Revolution, the number has of course been very much diminished, the order having been suppressed in more than one kingdom; but it is still one of the most numerous in the Roman Catholic Church. Many of the foreign missions are mainly supplied by the Franciscans, and they possess convents in almost every part of the world.

As a literary order, the Franciscans have chiefly been eminent in the theological sciences. The great school of the Scotists takes its name from John Duns Scotus (see SCOTUS), a Franciscan friar, and it has been the pride of this order to maintain his distinctive doctrines both in philosophy and in theology against the rival school of the Thomists, to which the Dominican order gave its allegiance. See THOMISTS. In the Nominalistic controversy, the Thomists were for the most part Conceptualists; the Franciscans adhered to the rigid Realism. See NOMINALISM. In the Free-will question, the Franciscans strenuously resisted the Thomist doctrine of 'predetermining decrees.' Indeed, all the greatest names of the early Scotist school are the Franciscans, St. Bonaventure, Alexander de Hales, and Ockham. The single name of Roger Bacon, the marvel of medieval letters, the divine, the philosopher, the linguist, the experimentalist, the practical mechanician, would in itself have sufficed to make the reputation of his order, had his contemporaries not failed to appreciate his merit. Two centuries later, the great Cardinal Ximenes was a member of this order. The Popes Nicholas IV., Alexander V., Sixtus IV., the still more celebrated Sixtus V., and the well-known Ganganelli, Clement XIV., also belonged to the institute of St. Francis. In history, this order is less distinguished; but its own annalist, Luke Wadding, an Irish Franciscan, bears a deservedly high reputation as a historian. In lighter literature, and particularly poetry, we have already named the founder himself as a sacred poet. Jacopone da Todi, a Franciscan, is one of the most characteristic of the medieval hymn-writers; and in later times, the celebrated Lope de Vega closed his eventful career as

a member of the third order of St. Francis. We may add that in the revival of art the Franciscan order bore an active and, it must be confessed, a liberal and enlightened part. See Wadding, *Annales Minorum Fratrum*, 8 vols.; see also Milman's *Latin Christianity*, vol. v.

FRANCISCO, SAN. See SAN FRANCISCO.

FRANCKE, AUG. HERM., a distinguished German philanthropist, founder of the Orphan Asylum and several educational institutions at Halle, was born at Lubeck in 1663. Having studied languages and theology with great application and success, he first attracted attention by his academical biblical lectures in Leipzig, begun about 1685. These were more distinguished for piety, warmth, and zeal, than for attention to the strict and dry orthodoxy then in vogue; and the reception they met with from the public brought on F. envy and persecution as a heretic. He thought proper to yield to the storm, and withdrew in 1690 to Erfurt. In 1692, he obtained the professorship of Oriental languages in the newly instituted university at Halle, where he subsequently held a professorship of theology. He also received the pastoral charge of the suburb of Glaucha. The ignorance and poverty of his parishioners gave the first impulse to his benevolent labors. To the neglected poor and children that came to him for alms, he gave instruction on stated days, and as others joined, paying a school-fee of a penny a week, and the numbers rose to some sixty, he divided them into classes, and thus laid the first foundation of his educational establishments. At the same time the thought suggested itself of an orphan asylum, and in 1698 he laid the foundation of a special building for the asylum. Some years after, he erected a *Pedagogium*, a Latin school, and a boarding establishment connected with it. In 1714, there were 1075 boys and 700 girls receiving instruction from 108 teachers under the direction of Francke. He also had a missionary institution for the East Indies. To erect and maintain all these establishments required large sums of money; and it is surprising how F. succeeded in obtaining it without assistance from government. But so high was his reputation for disinterested benevolence, and in such a practical way did he set about his undertakings, never appealing for the charitable aid of others till he had first effected something himself, that contributions flowed in from all parts of Germany, and even from abroad. F. also instituted an apothecary's shop and bookselling in connection with his other operations, and thus obtained a considerable income for their support. Nor amidst all these voluntary labors did he neglect his duties as professor and pastor; he preached and lectured regularly, and also found time to study and write. He died June 8, 1727.

Francke's Institution, as it now exists in Halle, embraces the orphan house and schools erected by F., together with others since added; the number of pupils amounting in all to upwards of 3500. Book-selling, printing, and a laboratory for the preparation and distribution of medicines are also carried on in connection with education. The revenues consist of the profits of this industry, of the income from some property in land and funds, and of an allowance of £6000 from the state. The education imparted retains its religious character, but the excessive number of prayers and the otherwise conventual and ascetic character of the discipline have been diminished.

FRANÇOIS, ST., is the name of two towns in the French West Indies.—1. St. F., in Guadeloupe stands on the Grande Terre, the more easterly of the twin islands into which the colony is divided by an arm of the sea known as Salt River. It contains about 6600 inhabitants, about 5600 of them having been slaves down to 1848, the epoch of emancipation under the French Republic.—2. St. F. in Martinique possesses a good harbor on the east coast. Of a population of 5966, 4272 had been slaves.

FRANCOLIN (*Francolinus*), a genus of birds of the family *Tetraonidae*, closely allied to partridges. They are natives of Europe, Asia, and Africa. One species only, the EUROPEAN F. (*F. vulgaris*), is found in the most southern parts of Europe.

FRANCONIA (Ger. *Franken*). This name was first applied to those districts on both sides of the Maine which were originally peopled by colonies of Franks, under Thierry, the eldest son of Clovis, who inherited the Germanic possessions of his father on the death of the latter in 511. Under the Merovingian and Carolingian dynasties, this province acquired a certain degree of preponderance in the state, and enjoyed the privilege of electing the king of the Germans within its own territories, and crowning the sovereign by the hands of its archbishop (Mayence), who was primate of the empire. In 911, Conrad, the Count or Duke of Franconia, for there is some doubt which of these titles was at that time borne by the ruler of the province, was raised to the throne; and a century later, after the ducal dignity had been recognized in F., the choice of the electors again fell upon the Franconian House, which, by its direct and collateral branches, gave kings and emperors to Germany from 1024, when Conrad II. began his reign, till 1250, when the indirect line of the Hohen-

stauffen family became extinct. During its connection with the crown, F. increased in extent and importance, while its great spiritual principalities of Mayence, Spire, Worms, and Würzburg acquired both wealth and political influence.

In the course of the following 200 years, the province underwent various modifications, and was sub-divided into numerous territories, as those of the Rhenish County-palatine, Nassau, Katzenelnbogen, Hainau, the landgraviate of Hesse, &c., until the name of F. was limited to the eastern portions of the ancient duchy, which included Würzburg, Fulda, Bamberg, Nürnberg, Hohenlohe, &c. In 1512, Maximilian I. re-established the circle of F., which then embraced the sees of Bamberg, Würzburg, and Eichstädt, Baireuth and Anspach, and several counties and cities. With the dissolution of the empire, the name of F. disappeared from among the political divisions of Germany; but since 1837 it has been revived in the kingdom of Bavaria (q. v.), where those portions of the ancient Franconian province, which in modern times have been known as the circles of the Upper Maine, Rezat, and Lower Maine, are now designated Upper, Middle, and Lower Franconia. Upper F. includes the north-east portion of Bavaria. It is watered by numerous rivers, as the Maine, Raab, Saale, &c., and is intersected by the Fichtelgebirge and by the hilly ranges of the Böhmer-Franken-, and Steiger-Wald. The valleys produce good crops and fruit, and the district is rich in minerals. Pop. (1880) 575,357; capital, Baireuth. Middle F., which abuts upon Württemberg, is intersected by branches of the Franconian Jura chain, but has few rivers of importance besides the Regnitz and Altmühl, which are connected by the great Ludwig Canal. It produces good wine, but is principally celebrated for its hop-gardens. Anspach and Nürnberg are the principal towns. Pop. (1880) 643,817. Lower F., with Aschaffenburg, which occupies the north-west part of Bavaria, is the richest and best cultivated of the Franconian circles, and is celebrated for the excellence of its wines, the Steiner and Leister. The district is noted for its mineral springs at Kissingen, Brückenau, Orb, and Wipfeld. Pop. (1880) 626,305; capital, Würzburg. Small portions of F. were ceded to Prussia in 1866. The pop. of the three F.s in 1875 was 1,758,048.

FRANC-TIREURS, bands of French soldiers that sprang into existence during the progress of the Franco-Prussian war (1870—1871). They did not form part of the regular army, and at first their military organization was very imperfect; but this defect was afterwards in some measure remedied. They exercised a species of guerilla warfare, attacking small detachments of the enemy, as also single travelers, baggage-trains, &c., their attacks being too often characterized by those savageries incident to this mode of warfare. They consisted mostly of the rural population; but their birth, education, clothing, arms, age, and even their aim, were almost in every case different. At first, they were not recognized by the Germans as having any military standing at all, and when seized they were shot; but after a time, when they received a better organization and co-operated with the regular French army, such recognition was accorded them.

FRANEKER, a handsome town of the Netherlands province of Friesland, on the canal between Harlingen and Leeuwarden. It was formerly the seat of a university founded in 1585 by the Frisian states on the suggestion of Prince William Louis, Count of Nassau, which ranked among its professors the eminent names of Vitringer, Schultens, Hemsterhuis, Valckenauer, and others. It was, however, abolished by Napoleon in 1811, and in 1816 was transformed into an atheneum, to which a physiological cabinet and botanic garden belong. There is here a remarkable Planetarium (q. v.), made in 1774—81 by Eisinga. Pop. (1879) 7222.

FRANGIPANI, an illustrious and powerful Roman House, which traces its origin to the 7th c., and attained the summit of its glory in the 11th and 12th centuries. In the early annals of Rome, several members of this family occupied important public offices, and seem to have taken a prominent lead in all matters of moment. In 987, Crescenzo Frangipani successfully vindicated the prerogatives of the Roman people against the encroachments of Pope John XV. The rivalry of the F. House with that of the Pietro Leoni, not only occasioned repeated civil wars in the state but likewise several schisms in the church. The lustre of their race was finally outshone by the two great patrician families, Colonna and Orsini, whose magnificence, power, and pretension far exceeded those of the greatest citizens of Rome. Two of the last of the F. who merit mention are Giovanni, who captured Conradin of Hohenstaufen, and delivered him, in 1268, to his sanguinary enemies; and Latino, Grand Inquisitor and Cardinal and Bishop of Ostia and Velletri. The origin of the name Frangipani is attributed to the family's benevolent distribution of bread in time of famine.—The Croatian family of the same name claim descent from the great original Roman House.

FRANK, FRANKING LETTERS. On the introduction of the uniform penny-postage on all inland letters in 1840 (3 and 4 Vict. c. 96), the privilege formerly enjoyed by peers and members of

the House of Commons, and many official persons, of 'franking,' as it was called, that is, sending and receiving letters duty free, was abolished; the statute 7 Will. IV. and 1 Vict. c. 32, by which this privilege had been recently regulated, being repealed by s. 68 of the first-mentioned act. The privilege was claimed by the House of Commons in 1660, when the post-office was first legally established (see *POST-OFFICE*), but it was afterwards dropped upon a private assurance from the crown that it should be allowed to members. The postmaster-general accordingly constantly issued a warrant directing the allowance, till the privilege was expressly conferred by statute 4 Geo. III. c. 24. In the days of franking, each member of either House of Parliament was entitled to send ten letters every day, not exceeding an ounce in weight each, to any place in the United Kingdom, and to receive fifteen, free. As it was not necessary that the letter should be either written by or to the privileged person, the privilege was greatly abused; and most persons whose memories reach back to the period when it existed, will remember family arrangements for taking advantage of it, by which the whole correspondence of the kindred, connections, and even the intimate acquaintances of a peer, or a member of parliament, was in general carried on duty free.

Up to the passing of the last-mentioned statute (12th July 1837), all that was requisite was that the member should write his name or title on the corner of the letter. From this time, however, till the abolition of the privilege, it was required that the whole address should be written by the member; that he should add not only his name, but the name of the post-town, and the day of the month; and what was most troublesome of all, that the letter should be posted on the day on which it was written, or the following day, and in a post-town within 20 miles of which the person franking was then actually resident. By this cruel regulation (7 Will. IV. and 1 Vict. c. 35, s. 9), the kindly custom of giving frank to friends, or leaving them with them for future use, was rudely interfered with, and the public mind reconciled to the final abolition of what many regarded as a time-honored abuse.

FRANKALMOIGNE (Lat. *libera elemosyna*, free alms) was a gift of lands to those who were consecrated to the service of God. By the ancient common law of England, a man could not alien lands which came to him by descent without consent of his heir, but he might give a part to God in free alms. It was an old Saxon tenure, and continued under the Norman revolution, through the great respect that was shown to religion and religious men. This is the tenure by which almost all the ancient monasteries and religious houses held their lands, and by which the parochial clergy and very many ecclesiastical foundations held them at this day. The statute of 12 Car. II. c. 24, which abolished the old tenures, specially reserved tenure in frankalmoigne. The condition on which lands in frankalmoigne were held was, that masses and divine services should be said for the grantor and his heirs, but no particular service was specified. At the Reformation, the nature of the services was changed, but the tenure was suffered to continue. A tenant in frankalmoigne did no fealty to his overlord, and in the event of failure to perform the service, the latter was not entitled to distrain, but might complain to the ordinary or visitor. In this respect, this tenure differed from tenure by divine service, i. e., where lands were given on condition of performing a specified service, as say a mass on a particular day, or distributing certain alms. In this case, the tenant was bound to render fealty, and the lord was entitled to distrain on failure to perform the service. But lands held in frankalmoigne were subject to the *trinoda necessitas*, of repairing highways, building castles, and repelling invasions. Frankalmoigne was a tenure, to be held of the grantor and his heirs; all lands, therefore now held in frankalmoigne, unless created by the crown, must have been granted before the reign of Edward I., for by *Quia emptores*, 18 Edw. I., all grants by subjects to be held of the grantor and his heirs are ineffectual. In Scotland, lands conveyed to the church in *puram elemosynam* were said to be mortified. See *MORTIFICATION*.

FRANKENBERG, a flourishing manufacturing town of the kingdom of Saxony, is situated on an affluent of the Mulde, 32 miles S.W. of Dresden. It has manufactures of cottons, woollens, silk-stuffs; also dye-works and cigar manufactories. In addition to the other elementary and advanced educational establishments, F. possesses a trade school and an agricultural seminary. Pop. (1880) 10,913.

FRANKENHAUSEN, a small town of Germany, in Schwarzbürg-Rudolstadt, stands on the Wipper, 27 miles N.N.W. of Weimar. It has a palace, a higher school, and a seminary for teachers. There are here very productive salt springs, a large sugar-refinery, with manufactories of cigars and articles in mother-of-pearl. In the neighborhood are anthracite mines. Pop. (1880) 4985. F. figures in history as the scene of a battle between the rebellious peasants under Thomas Münzer, 15th May 1525,

and the Saxon, Brunswick, and Hessian troops, in which the former were defeated.

FRANKENSTEIN, a small but active town of Prussia, in the province of Silesia, is situated on a height on the left bank of the Paase, 37 miles south-south-east of Breslau. Six miles south-west of F. is the mountain fortress of Silberberg (still existing, but not maintained as a fortress since 1860), the defences, bastions, and casemates of which are almost entirely hewn out of the solid rock. These works were constructed by Frederick the Great, in order to command the passage from Bohemia. Pop. (1880) 7861, who are engaged in the manufacture of broadcloth, linen, aquafortis, strawplait, saltpetre, &c.

FRANKENTHAL, a prosperous manufacturing town of Germany, in the Bavarian Palatinate, is situated on the Isenach, 16 miles north-north-west of Spire. From the town, a canal between 50 and 60 feet broad extends east to the Rhine, a distance of three miles. It has important cloth manufactures, cotton and linen weaving, and manufactures of gold and silver wire, and of needles, files, and tobacco. Pop. (1880) 9043.

FRANKFURT-ON-THE-MAIN (Ger. *Frankfurt am Main*), a city in the Prussian province of Hessen-Nassau, is situated on the right bank of the Main, in lat. 50° 6' N., and long. 8° 41' E. Till 1866, F. was the foremost, as it was the most ancient, of the four free cities of the German Confederation, and the seat of the Diet. The city lies in a wide and fertile valley at the mouth of the Main, and is encircled by a belt of villas, gardens, vineyards, and orchards. In respect of commerce and wealth, F. is one of the most important cities of Germany; pop. (1875) 103,315, of whom upwards of 7000 are Jews; with suburbs (1880) 137,600. F. is the center from which radiate public roads and railways to every part of Germany; while its site on the banks of the Main, 20 miles from its confluence with the Rhine, by affording it a direct channel of water-communication with the German Ocean, secures to it great advantages as a seat of commerce. Its central position has pointed it out from the earliest ages of the history of Germany as a suitable place for national meetings, and in 794 Charlemagne convoked a council here.

In 843, F. was made the capital of the eastern Frankish empire, and continued so till 889, when Arnulf transferred that honor to Ratisbon; in 1257, F. was raised to the dignity of a free city; and in 1356, Charles IV. confirmed by the famous 'Golden Bull' the right, which it had enjoyed since the days of Frederick Barbarossa, of being the place for the election of the emperors of Germany. The Guildhall, or *Roemer*, contains the *Wahlzimmer*, or Hall of Election, in which the Electors (q. v.) met to deliberate on the nomination of the emperors, and the *Kaisersaal*, or Imperial Hall, in which the newly elected monarch held his public dinner, at which he was waited upon by the counts and high officers of the empire, who held their respective domains and offices in right of their performing various acts of service on that occasion. Round this hall are ranged in niches the portraits of the emperors from Conrad to Leopold II. The Golden Bull is preserved among the archives. The ancient cathedral, St. Bartholomew's, contains the chapel in which the electors accepted the emperor after he had been anointed at the high-altar. F. still contains many old and narrow streets with high-gabled projecting houses, but its ancient walls and ramparts have been converted into pleasure-walks, and there are now broad quays, and wide handsome streets in the more modernized parts of the city. The gates of the famous *Juden-gasse*, which were closed at night to prevent the egress of the Jewish inhabitants, were razed at the time of the French occupation in 1806; and the street is now more than half demolished, almost the whole of the western side having been pulled down. F. is connected with its suburb, Sachsenhausen, which lies on the left bank of the Main, by three bridges (one dating from 1342, another finished in 1878), besides the railway bridge and a wrought-iron suspension bridge for foot passengers. There are fountains in several of the squares, one of which is adorned with a fine statue of Goethe, who was born at F., and another with a group commemorative of the invention of printing. F. possesses several good public libraries, museums, and galleries, and many charitable institutions. It derives great wealth from its banking transactions; the aggregate capital of its bankers, among whom the name of the Rothschilds has long stood foremost, is said to be about 20 millions sterling, and the annual transactions in bills of exchange about 12 millions sterling. Its manufacturing industry has greatly extended since the annexation of Prussia; to the former manufactures of snuff, tobacco, jewelry, printers' black, wax-cloths, and carpets, have been added type-founding, chemical works, and the manufacture of sewing-machines on a large scale. As a free city, F. possessed a small territory of about 39 square miles outside its precincts, and was governed by 2 burgomasters (elected annually), 4 syndics, a civic committee of 21 members, and a legislative chamber of 57 members; the highest court of appeal was the supreme tribunal at Lübeck. The Constituent Assembly elected in 1848 to frame a constitution for Ger-

many, held its sittings at F. At the outbreak of the Austro-Prussian war in 1866, F. chose the side opposed to Prussia. On the 16th July, General von Falckenstein entered the city, a fine of 31 millions of florins being imposed; and on the 18th October F. was formally incorporated with the Prussian state. It was in F. that peace was finally concluded between Germany and France in 1871, the treaty having been signed on the 10th May, in the Swan Hotel here, by Bismarck and Jules Favre.

FRANKFURT-ON-THE-ODER, the capital of an extensive Prussian circle of the same name in the province of Brandenburg, is a place of considerable trade, on the railway line between Berlin and Breslau, and about 50 miles east of the former city. F. lies in lat. 52° 22' N., and long. 14° 33' E. Pop. in 1880, 51,147. It is a handsome, well-built town, and has three suburbs, one of which lies on the right bank of the Oder, and is connected with the remainder of the town by a wooden bridge. Of the six Protestant churches, St. Mary's, founded in the 13th c., is the most worthy of notice, for its large organ, richly gilt wood-carvings, and fine stained windows. The university, founded in 1506, was incorporated in 1811 with that of Breslau, but F. still has its distinct gymnasium, with its branch-schools. Three great fairs are still annually held at F., but although they are still attended, as of old, by many Poles and Silesians, sales are less brisk than in former times. F. has manufactures of ironware, porcelain and pottery, sugar, felt, bone-dust, liquors, chocolate, paper, leather, silk, and wool stuffs. Its situation on a navigable river, connected by canals with the Vistula and the Elbe, affords great commercial and social advantages, which have rendered it a place of importance from a very early period. It was a flourishing member of the Hanseatic League, and during the middle ages it suffered frequently at the hands of marauding enemies. It was besieged in 1430 by the Hussites, in 1450 by the Poles, and in 1477 by the Duke of Sagan. In the Thirty Years' War, it was frequently taken by both parties, and at the beginning of the present century it suffered severely at the hands of the French. F. is the seat of the administrative government, judicial tribunal, council of nobility, and boards of taxation for its circle. The village of Kunersdorf, 4½ miles from F., was the scene of a great battle, fought August 13, 1759, between Frederick the Great and the Russo-Austrian forces, in which the former was compelled to retreat with great loss.

FRANKINCENSE (*thus*), a name employed to designate various fragrant resinous substances which diffuse a strong fragrance in burning, and are on that account used in certain religious services. There is good reason to believe that the frankincense of the Jews, and also of the ancient Greeks and Romans, was chiefly or entirely the substance now known as *Olibanum* (q. v.), the produce of an Indian tree, *Boswellia serrata* or *thurifera*. See BOSWELLIA. It was formerly supposed to have been obtained from the *Juniperus Lycia*, which is now believed not to yield any such product, and is a native of the south of Europe, whilst the prized frankincense of the ancients was brought from the East.—Several trees, however, of different natural orders, yield substances used as frankincense instead of olibanum, in different parts of the world, as several species of *Icica* and of *Croton* in America; and the silver fir (see FIR) in Europe, the resinous product of which is the COMMON FRANKINCENSE of the pharmacopœias, although in the shops, concrete American turpentine is very often sold under this name. It is used in the composition of stimulating plasters, &c. *Burgundy pitch* is made from it. It is a spontaneous exudation from the tree, hardening by exposure to the air, and generally of a whitish or pinkish color, with a rather agreeable odor and a balsamic taste.

FRANKLIN The franklin, or, according to the old spelling, the frankelín, was the English freeholder of former times, who held his lands of the crown, free (frank) from any feudal servitude to a subject-superior. Chaucer's *Franklin's Tale*, and still more his description of the franklin in the prologue to his immortal *Pilgrimage*, have rendered him a classical character. In the whole circle of our literature there is probably no more perfect picture of the person, habits, and surroundings of a jovial old country gentleman. His beard was white as a daisy, his complexion sanguine, he loved a 'sop in wine,' and woe to his cook if his sauce were not poignant and sharp; in a word, 'he was Epicurus' oven son.' But the franklin's luxuries were not intended for his own enjoyment alone, for 'a householder, and that a great, was he.' His table stood 'in his hall alway,' 'ready covered all the longe day;' and

Withouten baked meat never was his house,
Of fish and flesh, and that so plenteous,
It snowed in his house of meat and drink.

Nor was it only in dispensing good cheer that the franklin fulfilled the functions of the country gentleman of his day. At sessions, he was 'lord and sire,' and full often time he had been 'knight of the shire.' He had been sheriff too, and a countour and vavassour; though what these latter offices were, is a subject of contro-

versy amongst the commentators. 'The dress of the franklin, according to the Duke of Sutherland's MS.,' says Mr. Saunders, in his excellent little book called *Cabinet Pictures of English Life* (p. 204), 'was a surcoat of red lined with blue, with bars or stripes of fringe or lace over it. He wore a small blue hat turned up, and black boots.' Chaucer adds to his attire a knife or dagger called an 'anelace,' and a 'gipciere' or silk purse, 'white as morrow [morning] milk,' at his girdle. Mr. Saunders mentions (*at sup.*) that in the *Metrical Chronicle* of Robert de Brune, the franklin of an earlier period (13th c.) is ranked immediately after earls, barons, and lords, and was evidently a person of great consideration. Such, as we have seen, was very much his position in Chaucer's time, but he seems to have fallen in dignity, and we find him in much lower company in Shakspeare's day. In *The Winter's Tale* the clown is made to say (Act v. scene 2):

Not swear it, now I am a gentleman
Let boore and franklin say it, I'll swear it.

From other passages it would seem that his position had come to correspond to that of the well-to-do yeoman. In 1 Henry IV., Act ii. scene 1, we hear of a franklin 'in the wold of Kent hath brought three hundred marks with him in gold;' and *Cymbeline* says (Act iii. scene 2), 'Provide me presently a riding suit, no costlier than is fit a franklin's housewife.' There seems no reason to think, however, that Dr. Johnson's remark that franklin is 'not improperly Englished a gentleman servant,' is warranted by his position at any period, and it certainly is not by the passage which he quotes from the *Fairy Queen*:

A spacious court they see, &c.,
Where them does meet a franklin fair and free.

FRANKLIN, BENJAMIN, a distinguished American statesman and natural philosopher, was born at Boston January 17, 1706. His parents were poor, and had a family of seventeen children, he being the fifteenth. Josiah Franklin, his father, had left England in 1685, and settled in America, where he followed the business of soap-boiler and tallow-chandler. At the age of eight, F. was sent to school, where he displayed great aptitude for learning. At twelve, he was apprenticed to his step-brother James, who had set up a printing-shop in the place, and he soon acquired considerable proficiency at the trade. He was passionately fond of reading, and all the time he could spare, he devoted to the perusal of such books as he could lay his hands on. He early attempted poetry, and when, in 1720, his brother started a newspaper, he contributed a number of anonymous articles to it; but on the fact being discovered, his brother treated him very harshly. After one of the frequent quarrels with his brother he determined to quit him; and accordingly, without the knowledge of his family, he left Boston and proceeded to New York; but not finding employment there, he went next to Philadelphia, where he succeeded in procuring a situation in a printer's shop. Here he attracted the attention of Sir William Keith, the governor of Pennsylvania, who advised him to set up a printing-establishment of his own. Thinking this good advice, he set out for England, with a view to obtain the necessary plant. Finding himself, however, deceived in his expectations of assistance from Keith, and having no resources of his own, he was compelled to take employment in London, where he resided for about a year. On his way back to Philadelphia in 1726, he made the acquaintance of a merchant named Denham, who gave him the situation of book-keeper in his office; but Denham dying soon after, F. went back to his old trade, and, with the assistance of some friends started in business for himself. In 1730, he married a Miss Read, with whom he had become acquainted previous to his visit to England. Matters now prospered with F.; he became the proprietor and editor of a newspaper (*The Gazette*) which attained a high degree of popularity, and projected in 1732 *Poor Richard's Almanac*, in which appeared the well-known maxims afterwards published under the title of *The Way to Wealth*, and translated into various languages. Through the instrumentality of F., a public library was founded in 1732, the first established in Philadelphia. He also founded in 1738, the first association for extinguishing fires, and at a later period the first company for insurance against fire; and in many other ways he contributed to the social and material progress of the city of his adoption. Among the public offices to which he was appointed were those of clerk to the General Assembly of Pennsylvania in 1736; postmaster of Philadelphia in 1737; representative of Philadelphia in the Assembly 1747. In 1753, he was appointed deputy postmaster-general for the British colonies. In 1757, he was sent to England to settle some matters for the Assembly, and so ably did he perform his task, that Massachusetts, Maryland, and Georgia severally appointed him their English agent.

Notwithstanding the multiplicity of his public duties, he found leisure to pursue his scientific investigations with such success as to gain for himself a lasting name in the world of science, as well as to merit the gratitude of the community in general. In 1752, he discovered the identity of electricity with lightning, and turned his discovery to account by publishing a plan for defending

houses from lightning by the use of pointed conductors. He likewise made important discoveries with regard to the laws that regulate the electric fluid, a subject hitherto very imperfectly understood. His renown was spread over the whole civilized world, and honors were heaped upon him by the various learned societies of Europe. The Godfrey Coley gold medal was bestowed upon him by the Royal Society of London, which also nominated him one of its members. The universities of Oxford, St. Andrews, and Edinburgh respectively conferred upon him the degree of D.C.L. He was made an associate of the Academy of Sciences at Paris, as Leibnitz and Newton had been before him.

During his residence in England he became intimate with some of the most distinguished men both of Britain and of the continent; his correspondence with them indicates the combination in a remarkable degree of a cultivated mind with a vivid imagination. In 1762 he returned to America; but new difficulties arising between the mother country and the colonies, which determined the Assembly to demand the establishment of a central government, he was again despatched to England as its agent. He strongly opposed the stamp act, and was examined at the bar of the House of Commons in 1766, when the repeal of that offensive measure was proposed. In consequence of the position he assumed on this occasion, he was deprived of the postmastership, and treated very harshly by the ministry. Despairing of bringing about any reconciliation between the disputants, he returned to Philadelphia in 1775, where the Congress was at that time assembled. He was elected a delegate to it; and from that time he exerted himself to the utmost to obtain a declaration of the independence of the thirteen American states. This declaration was pronounced by Congress on the 4th July 1776, and F. was appointed United States minister at the court of France, where he succeeded in inducing the French government to form an offensive and defensive alliance with the States. On the 20th of January 1782, F. had the supreme satisfaction of signing at Paris, along with the English commissioners, the treaty of peace by which the independence of the American colonies was assured. Returning to America in 1785, he was successively chosen member and president of the supreme executive council for the city of Philadelphia, and in 1787 delegate for Pennsylvania to the convention for the revision and emendation of the Articles of Union. In 1788, he retired from public life, and died April 17, 1790, at the advanced age of 84. The Congress, as a testimony of the gratitude of the thirteen states, and of their sorrow for his loss, appointed a general mourning throughout the States for the period of two months.

F., in all his labors, was ever actuated by an intense desire to promote the well-being and happiness of his fellow-men; and few have been more successful in their aims. From poverty he rose to wealth, and from ignorance and obscurity to extensive erudition and honorable renown; gaining for himself the admiration of Europe and the gratitude of America.

In person, F. was about 5 feet 9 or 10 inches in height, and well and strongly made. He had a fair complexion and gray eyes, while his manners were extremely winning and affable. None of his descendants bears his name; the last who did so being his grandson, William Temple Franklin, who died in 1823. There are many descendants of his daughter, who married a Mr. Bache.

The works of F. appeared in London in 1806. His memoirs, &c., were published in 1817; a complete edition of his works, in 1836-40. In 1874, Bigelow published a new edition of F.'s autobiography (originally published in a French translation), from the original autograph. See Parton's *Life and Times of F.*, 1864.

FRANKLIN, REAR-ADMIRAL SIR JOHN, an English naval officer of distinguished reputation, was born at Spilsby, in Lincolnshire, April 16, 1786. He was descended from a long line of freeholders, and was the youngest son of a respectable yeoman. F. received the rudiments of his education at St. Ives; afterwards he spent two years at the grammar school of Louth. It is stated that he was intended for the church, but as he displayed a decided predilection for the sea, his father wisely abandoned opposition to his choice of a profession, and procured him, in 1800, a midshipman's post on board the *Polyphemus* line-of-battle ship. In the following year, F.'s ship led the van in the desperate battle of Copenhagen. Two months after, he was removed to the *Investigator*, then fitting out under command of Captain Flinders, for discovery and survey of the Australian coast. In this expedition, F. had the companionship of the distinguished botanist Robert Brown, and of his coadjutor Ferdinand Bauer, and from them he learned the great importance of the natural sciences, in the promotion of which he ever afterwards took a deep and intelligent interest. On his return to England, F. was appointed to the *Bellerophon*, in which he acted as signal midshipman in the battle of Trafalgar (1805), and had the good-fortune to escape unhurt. He subsequently served in the *Bedford* on various stations, and took a distinguished part in the attack on New Orleans in

1814. In 1819, F. was despatched by government to Hudson's Bay, with orders to make his way thence to the Arctic Sea, and survey as much of the coast as possible. In the course of this expedition, which lasted about three years and a half, F. traveled 5550 miles under circumstances of the greatest hardship and privation, to which more than half of his companions succumbed. But the gain to science was great, alike from the carefulness and extent of the physical surveys of the mouth of the Coppermine River, and eastward along Coronation Gulf, and from the attention devoted to the natural productions of these inclement shores.

On his return, in 1822, F. was made post-captain, and elected a Fellow of the Royal Society. In 1825, he co-operated (overland) with the sea-expeditions of Captains Parry and Beechey, and surveyed the North American coast from the mouth of the Coppermine westward to about Point Beechey. F.'s discoveries now extended over 44 degrees of longitude, or more than a third of the distance between Baffin's Bay and Behring's Strait. For these valuable explorations, in which he was engaged until 1827, he received the honor of knighthood from his sovereign, and the degree of D.C.L. from the university of Oxford, while the French Geographical Society awarded him their gold medal, and at a subsequent period he was elected corresponding member of the Institute of France. F. next took an active part in the Greek war of liberation. In 1836, he was appointed governor of Van Dieman's Land, where his wise and moderate conduct secured for him the warm approbation both of the government and the colonists. The latter established a college and philosophical society in his honor; and years after, they testified that the memory of his rule was still gratefully cherished, by subscribing £1600 towards an expedition designed for his rescue. In May 1845, F., now bordering on his 60th year, but with physical and mental powers undiminished in vigour, started with the *Erebus* and *Terror* on his last and ill-fated expedition to discover the North-west Passage. The last time that the vessels were seen was in July of the same year. To enter into the history of the efforts undertaken for the relief or discovery of the fate of F. would be out of place here. It is sufficient to say that in the course of eleven years upwards of twenty separate expeditions, at the cost of about a million sterling, were sent out to look for the missing crews; and the discoveries of these expeditions added more to our knowledge of the arctic regions than all previous explorations had done. See NORTH-WEST PASSAGE. It was not until 1859 that the fate of F. was ascertained by the commander of a little vessel fitted out by Lady Franklin, after hope had been declared hopeless by all else. It then appeared that F. had died on the 11th June 1847, fortunately before his sympathetic heart had been lacerated by witnessing the awful sufferings of his men. F. was one of the boldest and most persevering explorers, and from the work ascertained to have been done before the collapse of the expedition, is now fairly regarded as the discoverer of the North-west Passage. Additional light was thrown on the fate of his crews by a memorable sleighing expedition under Lieutenant Schwatka in 1879-80.

FRANKLIN, JANE, LADY, the second wife of Sir John F., to whose unwearied energy, devotion, and hopefulness, when hope had sunk in all other hearts, we are indebted for the knowledge of the fate of her gallant husband, was the daughter of John Griffen, Esq., of Bedford Place, London, and was married to Sir John Franklin in November 1826.

In 1848, when, owing to the long absence of news about the expedition of the *Erebus* and *Terror*, fears began to be entertained about its safety, Lady F. offered large rewards to any persons who should discover and relieve the missing voyagers, or who would make exertions with that end in view. From that time until 1857, when she fitted out the *Fox*, under McClintock, whose discoveries set all doubts about the fate of her husband's expedition at rest, Lady F. never rested in her efforts to incite by voice, pen, and purse, her own countrymen and Americans, to search for the missing ships. Her interest in Arctic exploration never flagged up to her last illness and death in 1875.

FRANKMARRIAGE (*liberum maritagium*) was a species of estate tail existing by the common law of England; for where a man on the marriage of his daughter or cousin, gave lands to be held in frankmarriage, this implied a gift in especial tail, to the donees and heirs of their bodies. This tenure was called *liberum maritagium*, to distinguish it from other species of estates tail (*Co. Litt.* 94 b). Four things were necessary to a gift in frankmarriage: 1. That it must be in consideration of a marriage, but it might be as well after as before a marriage. 2. That the donee with whom it is given be of the blood of the donor. 3. That the donees should hold of the donor. Hence a gift in frankmarriage by a subject became impossible after the statute of *Quia emptores*. 4. That the donees should hold for four generations. Therefore a gift in frankmarriage with a reservation of a remainder to a stranger, or a devise by will, was bad.

FRANK-PLEDGE, a law prevailing in England before the Norman Conquest, whereby the members of every tything were

responsible for the good-conduct of each other. This responsibility, according to Mr. Hallam, consisted in every ten men in a village being answerable each for the others, so that if one committed an offence, the other nine were liable for his appearance to make reparation. Should the offender abscond, the tything, if unable to clear themselves from participation in the crime, were compelled to make good the penalty. This law has been ascribed to Alfred the Great; but it would appear to have been in existence at a much earlier period. Mr. Hallam, *Middle Ages*, ii p. 80 (ed. 1841), observes: 'The peculiar system of frank-pledges seems to have passed through the following very gradual stages. At first, an accused person was bound to find bail for standing his trial. At a subsequent period, his relations were called upon to become securities for payment of the compensation and other fines to which he was liable; they were even subject to be imprisoned until payment was made, and this imprisonment was commutable for a certain sum in money. The next usage was to make people already convicted, or of suspicious repute, give securities for their good-behavior. It is not till the reign of Edgar that we find the first general law, which places every man in the condition of the guilty or suspected, and compels him to find a surety who shall be responsible for his appearance when judicially summoned. This is perpetually repeated and enforced in later statutes during his reign and that of Ethelred. Finally, the laws of Canute declare the necessity of belonging to some hundred and tything, as well as of providing sureties.'

The *Court of Frank-pledge*, or *Court-leet*, is a court of record held once in the year, and not oftener, within a particular hundred, lordship, or manor, before the steward of the leet: being the king's court granted by charter to the lords of those hundreds or manors. All freeholders resident in the jurisdiction are bound to attend this court; but persons under twelve and over sixty years of age are excused, and by the statute of Marlbridge, 52 Hen. III. c. 10, all prelates, peers, and clergymen, and women are discharged from attendance. It was also the custom to summon all the king's subjects to this court, on attaining years of discretion, to take the oath of allegiance. The business of this court was to present by jury all crimes committed within their jurisdiction, and to punish all trivial misdemeanors. This court has practically fallen into desuetude, and the business is discharged by the justices of the peace at general and petty sessions. See Blackstone's *Commentaries*. Originally, the business of the court frank-pledge was confined to the taking securities or free pledges for every person within the jurisdiction; but this practice having fallen into disuse, the court gradually acquired a criminal jurisdiction, concurrent with that of the sheriff's tourn. '*Magna Charta* distinguishes between the tourns or leets of sheriffs and the view of frank-pledge; limiting the former to twice a year, and the latter to once. In the more ordinary sense, frank-pledge and leet are synonymous, as appears from the style of tourns and other leets, which in court-rolls are usually denominated *curia* or *visus franci plegii*. But when free pledge is used, as in *Magna Charta*,' it should be understood in a strict and particular sense.'—*Co. Litt.* by Hargrave, 115 a, note 10.

FRANKS (i. e., freemen) was the name assumed by a confederation of German tribes that appeared on the Lower Rhine in the 3d c., and afterwards overthrew the Roman dominion in Gaul. It was only the name, however, that was new; the individual tribes composing the confederation had been known on the Rhine as early as the time of Augustus. The most important of these were the Sigambri, Chamavi, Amsivarii, Chatti, Chattiarii and Bructeri of the time of the first emperors. In the 3d and 4th centuries, hordes of them began to pour through the Low Countries into Gaul, until at last the country became their prey. After the middle of the 4th c., they appear divided into two groups, the Salians—either from the old Ger. *Sal*, or the river Sala (*Yssel*)—and the Ripuarians (*ripa*, the bank), the first inhabiting Holland and the Low Countries, the last on both sides of the Rhine as far up as the Main. Each group had its own laws, afterwards committed to writing (*Lex Saliica* and *Lex Ripuariorum*). Like the two peoples, these laws differ little even in detail. The F. were a mobile, well-endowed race, forming in language and art the transition from the Low Germans to the High; and they compose to this day the ground of the population of the west of Germany as far as the Neckar, Main, Murg, and Lower Alsace, as well as the chief Germanic element of the population of Northern France. For the later history of the Franks, see articles CLOVIS, CARLOVINGIANS, CHARLEMAGNE, FRANCE, MEROVINGIANS, &c.

FRA'NZENSBRUNN, or FRANZENSBAD, a small village and well-known bathing-place in Austria, on the north-western frontier of Bohemia, three miles north-west of Eger, is situated amid low bare hills, and consists of four rectangular streets lined with trees. It has four cold mineral springs, chiefly of alkaline chalybeate water, deemed highly efficacious in the cure of serofulous complaints and diseases of the skin, and used principally for drinking, but also for bathing purposes, in which case

the water is heated to a temperature of 90° to 98° F. Nearly 200,000 bottles of these waters are exported annually. F. has also mud and gas baths.

FRANZ-JOSEF LAND, an archipelago in the Arctic Ocean, north of Nova Zembla, just beyond the parallel of 80°. Its land-masses are mountainous, at least one peak being 5000 feet high. The archipelago was discovered by the Payer-Weyprecht expedition in 1873, and named after the Austrian emperor. It was visited by the *Willem Barents* in 1879, and the south coasts were explored by Leigh Smith in 1880.

FRASCA'TI, a beautiful town about eight miles east-south-east of Rome, with a population of 7000. It stands on the lower heights of the Alban Hills, not far from the site of ancient Tusculum, which was burned and ruined by the Romans in 1191 A.D. The chief attractions of F. are its lovely villas and salubrious air, which render this resort in the Alban Hills the most fashionable *villeggiatura* in the vicinity of the Eternal City. The most splendid of these summer residences are the villas Aldobrandini, also known as Il Belvedere, from its commanding and noble prospect; those of Mondragon and Taverna of the Borghese family; the villas Pallavicini and Piccolomini.

The cathedral contains a tablet to the Cardinal of York, for many years bishop of this diocese, and another to his brother, Charles Edward, the Young Pretender, who died here in 1788.

FRASER, SIMON. See LOVAT, LORD.

FRASER RIVER, the principal stream of British Columbia, comprises in its basin the far greater part of the colony. The F. R. proper has its origin in the union of two branches, the more important of which receives its waters from a series of lakes that lie in lat. 54°—55° N., long. about 124° 50' W., flows in a general south-east direction for 260 miles, and then unites with the other branch, which has its source near Mount Brown, in the Rocky Mountains, lat. 53° N., long. 118° 40' W., flows north-west, and is 200 miles in length. The point of confluence is near Fort George, in lat. about 53° 25' N., and in long. about 122° 40' W., and hence the F. R. flows in a generally southern direction through nearly the whole length of the colony, and after a total course of 740 miles it falls into the Gulf of Georgia between Vancouver's Island and the mainland, barely to the north of the international boundary of 49° of latitude. Its chief affluents are the Stuart and the Chilcotin on the right, and the Thompson on the left.

Between the Stuart and the Chilcotin, and on the same side, the F. R. is joined by an affluent, which is rather of historical interest than of physical importance—the West Road River, which took its name from its having been ascended by Sir Alexander Mackenzie, on his adventurous journey of 1793 from the Hudson's Bay Territories to the Pacific Ocean. The F. R. is practicable for steamboats as far up as Fort Hope, a distance of about 150 miles from its mouth, while about half the distance, as far as New Westminster, it is navigable for large ships. Above Fort Hope, all intercourse is more safely and conveniently conducted by land; and even the aborigines, as their trails still testify, appear to have yielded to the same necessity.

In 1857, the F. R., in its auriferous diggings and washings, began to stand forth as the rival of California and Australia. Since then, the discoveries, originally confined to the lower basin, have steadily become at once more extensive and more productive. Eastward on the Thompson, and more especially northward among the upper waters of the great artery of the country, the precious deposit has sometimes given almost fabulous returns. The mining operations here are, however, almost wholly in the hands of Chinese and Indians. It was estimated that during the year 1875 they secured gold to the amount of 50,000 dollars (over £10,000). Specimens of silver have also been found on the F. R., so rich as to justify the construction of extensive works. Happily for the country, the days of easy gains and wicked waste have passed away. Since 1862, washings and surface diggings have been succeeded by systematic mining and steady labor. The F. R., its tributaries, and the numerous lakes communicating with them, furnish great facilities for the transport of timber. The lower Fraser country is especially densely wooded. A steamer runs as far up the river as Yale. The salmon of the F. R., of which there are five species, are justly famous.

FRA'SERA, a genus of plants of the natural order *Gentianeæ*, with a 4-partite calyx and corolla, 4 stamens, and a 2-valvular capsule. *F. Walteri*, a native of Carolina, Virginia, and great part of the basins of the Ohio and Mississippi, is often called American Calumba, the root being imported into Europe under that name. It is a pure and valuable bitter, similar in its effects to gentian. The stem is herbaceous, erect, 3—6 feet high; the leaves oval, oblong, opposite and whorled; the flowers greenish yellow. The plant is a biennial. It grows in marshy places.

FRA'SERBURGH, a burgh of barony and regality and seaport on the north coast of Aberdeenshire, 42 miles north of Aberdeen. It stands on the north-west side of a bay two miles in depth im-

mediately south of Kinnaird's Head (supposed to be the *Taiyalorum Promontorium* of the Romans), on which is the Wine Tower, an old castle with a cave below. The town, originally called Faithly, was made a burgh of barony by Queen Mary in 1546. Its name was changed into Fraserburgh (in honor of its proprietor, Sir Alexander Fraser of Philorth) by King James VI. in 1592; and the same king, in 1601, erected it into a free port, free burgh of barony, and free regality.

The streets are wide and clean, with substantial houses. Pop. of parish in 1881, 7552, annually increased to 10,000 during the herring-fishing in July and August. It is possessed of one of the best harbors on the east coast, which has lately been greatly extended, and has a patent slip attached to it. The chief exports are oats, barley, meal, potatoes, cured herrings, and cod. F. is now one of the most successful herring-fishing stations on the east coast of Scotland, the average number of boats being between 700 and 800. Since 1865, it has been connected with Aberdeen by railway. F. has a handsome cross and town-house in the principal square, and a spacious hall belonging to the Harbor Commissioners. Sir Alexander Fraser, in 1592, obtained a charter for the establishment of a college and university here, but the plan was never carried out.

FRASIER, a strawberry flower, is used by Scotch heraldic writers as synonymous with a cinquefoil; as in blazoning the coat of the Frasers, *Azure three frases* (Nisbet, i. p. 388).

FRATE'RCULA. See PUFFIN.

FRATICE'LLIANS, or FRATICELLI ('Little Brethren'), a sect of the middle ages, which may be regarded as an embodiment, outside of the medieval church, of the same spirit to which is due, within the church, the Franciscan order with its many offshoots. The Italian word *Fraticelli* originally was the popular name of the Franciscan monks; but, in the progress of the disputes which arose in the order (see FRANCISCANS), the name was specially attached to the members of the rigorist party, and eventually to those among them who pertinaciously refused to accept the pontifical explanations of the monastic rule, and, in the end, threw off all subjection to the authority of the church. Several of the popes, especially Gregory IX. and Nicholas III., attempted to reconcile the disputants. Pope Celestine V. granted permission to the rigorists to form for themselves a separate organization, in which the rule of St. Francis might be observed in all its primitive and literal rigor. The suppression of this order by Boniface VIII. appears to have furnished the direct occasion for the secession of the extreme party from the church. They openly resisted the authority of the pope, whom they proclaimed an apostate from the faith. The party thus formed was increased by adhesions from other sectarian bodies, as the 'Beghards' and the 'Brethren of the Free Spirit' (see FREE SPIRIT). In vain Clement V., in the council of Vienna (1311—1312), put forward a new declaration regarding the rule of St. Francis. They still held their ground, especially in Sicily, Central and Northern Italy, and Provence. John XXII., against whom they sided actively with Lewis of Bavaria, condemned them by a special bull in 1317, and again in a similar document directed against Henry de Ceva, one of their chief leaders in Sicily.

From these sources we learn that they regarded the existing church as in a state of apostasy, and claimed for their own community the exclusive title of the Church of God. They forbade oaths, and discountenanced marriages. They professed a divine mission for the restoration of the Gospel truth. They held that all spiritual authority was forfeited by sin on the part of the minister. It would even appear that they proceeded so far as to elect for themselves a pope, with a college of cardinals, and a regular hierarchy (Wadding, *Annal. Min. Fratrum ad an. 1374*, n. 20). Their principles, in a word, seem to have partaken largely of the same fanatical and anti-social tendencies which characterized the Brethren of the Free Spirit; and in common with them, the F. were the object of a rigorous persecution about the middle of the 14th century. The principles of this sect formed the subject of a public discussion at Perugia in 1374 between them and a Franciscan monk named Paolucci, which appears to have ended in their discomfiture. They still maintained themselves, nevertheless, in Central Italy, down to the 15th c., when John de Capistran received a commission to labor for their conversion in the March of Ancona; but before the beginning of the following century, they seemed to have disappeared altogether. See Mosheim, *De Beghards et Beguinabus* (Lipsie, 1790); Milman's *Latin Christianity*, vol. v.; Herzog's *Real-Encyclopædie*.

FRATTA-MAGGIO'RE, a town of Italy, six miles north-east of the city of Naples, has extensive rope-works, and furnishes great quantities of strawberries for the market of the capital. Silk-worms are here reared in great quantities. Pop. about 11,000.

FRAUD. By the laws of all civilized nations fraud invalidates obligations. In order to produce this effect, however, it is neces-

sary that the misrepresentations, or other dishonest manoeuvres of the offending party, shall have induced the other to enter into the agreement or contract, and that he would not otherwise have consented. Fraud of this description on the one side produces *error in essentialibus* on the other, and where such error exists there is no consent. But as consent is of the essence of the contract, there is here no contract at all; i. e., the contract, or pretended contract, is, as lawyers say, null *ab initio*. It is not necessary that the fraud which thus gives birth to the contract shall have consisted in positive misrepresentation, or even in studied concealment; and it is well laid down in the case of an English sale, that where the purchaser labored under a deception, in which the seller permitted him to remain, on a point which he knew to be material in enabling him to form his judgment, the contract was void. But there is another kind of fraud which, though it be not actually the cause of, is incident to, the contract, and which though it does not annul the contract, gives rise to an action for damages or restitution by the party deceived. The distinction between these two kinds of fraud was well-known to the civilians, the first species being described by them as that '*quod causam dedit contractui*,' that is to say, which causes the contract; the second as that '*quod tantum in contractum incidit*,' which is incident to, or accompanies the contract, but independently of which the contract would have been entered into (Voet. lib. 4, tit. 3, 3).

There is another very important element to be taken into account in judging of the character, and determining the legal effects of a fraud, viz., whether it proceeded from one whose position was such as to impose upon him the obligation of making the discovery. In illustration of this principle, the following case was put by Lord Thurlow in *Fox v. Mackreth* (2 Bro. Ch. R. 420): 'Suppose that A, knowing there to be a mine on the estate of B, of which he knew B was ignorant, should enter into a contract to purchase the estate of B for the price of the estate, without considering the mine, could the court set it aside? Why not, since B was not apprised of the mine, and A was? Because A, as the buyer, was not obliged, from the nature of the contract, to make the discovery. . . . The court will not correct a contract merely because a man of nice honor would not have entered into it; it must fall within some definition of fraud. The rule must be drawn so as not to affect the general transactions of mankind.' Neither will the commendations usually bestowed on their commodities by tradesmen be regarded as fraudulent statements, so long as they are simply extravagant in degree; but if positively at variance with facts known to them, they will not be permitted to enjoy the protection which custom has extended to ordinary 'puffing.' The same principle will yield the converse result wherever a relation of peculiar confidentiality exists between the contracting parties. Here courts of law require what is called *uberrima fides*, the fullest measure of good faith, to validate the transaction. As an illustration, may be mentioned a case in which the managing partner of a firm purchased the share of his co-partner for a sum which he knew from the accounts, of which he had the entire superintendence, to be inadequate, but the inadequacy of which he concealed. The transaction was reduced, Sir John Leach, V. C., remarking that 'the defendant being the partner whose business it was to keep the accounts of the concern, could not, in fairness, deal with the plaintiff for his share of the profits of the concern without putting him in possession of all the information which he himself had with respect to the state of the accounts between them.'—*Maddeford v. Austwick* 1 Gini. R. 89.

In addition to direct misrepresentation, and concealment in circumstances in which open dealing was a duty, fraud may be perpetrated by taking advantage of the imbecility of the party who has been led into the contract, and still more flagrantly by inducing this imbecility by intoxication or otherwise. See CONCEALMENT, ERROR, MISREPRESENTATION, CONTRACT. In addition to the ordinary English sources of information, we may refer to the extensive and learned *Traité du Dol et de la Fraude*, par J. Bédarride, 3 vols. (Paris, 1852).

FRAUNHOFER, JOSEPH VON, a distinguished practical optician, was born at Straubing, in Bavaria, 6th March 1787. In 1799 he was apprenticed to a glass-cutter in Munich, and in 1806 was received, as a working optician, into the establishment of Reichenbach and Utschneider at Benedictbeurn (afterwards, in 1819, removed to Munich). While there, he acquired considerable wealth through his inventions, and soon afterwards became proprietor of the establishment. He invented a machine for polishing parabolic surfaces, and was the first who succeeded in polishing lenses and mirrors without altering their curvature.

His prisms also were celebrated, being free from the blebs and striæ which are so often seen in those of English manufacture. His inventions are numerous, and include a 'heliumeter,' a 'micrometer,' an 'achromatic microscope,' besides the great parallax telescope at Dorpat. But that which has rendered F.'s name celebrated throughout the scientific world, is his dis-

covery of the lines in the Spectrum. He died at Munich on the 7th of June 1826.

FRAUNHOFER'S LINES. See SPECTRUM.

FRAUSTADT (Polish, Wszowa), a town of Prussia, in the government of Posen, is situated in a sandy plain on the Silesian frontier 55 miles northwest of Breslau. It has important grain markets, and near it are many windmills. Pop. (1880) 6755.

FREDERICIA, a seaport and fortress of Denmark, is situated on the east coast of the province of Jutland, on a projecting tongue of land, at the northern entrance to the Little Belt. It is fortified with nine bastions and three ravelins on the landside, and with two bastions towards the sea. It has several ecclesiastical edifices, a hospital, and a custom-house, at which toll used to be paid by ships passing through the Little Belt. Tobacco is grown and manufactured here. Pop. (1870) 7186.

FREDERICK (Ger. FRIEDRICH) I., OF GERMANY.—Frederick I., Emperor of Germany, surnamed BARBAROSSA (Red-beard), was born in 1121, succeeded his father, Frederick Hohenstaufen, as Duke of Swabia in 1147, and his uncle, Conrad III., as emperor in 1152. He was one of the most enlightened and powerful rulers who ever swayed the imperial sceptre. In his desire to emulate Charlemagne, and to raise the secular power of the empire in opposition to the arrogated supremacy of the papal chair, he was brought into constant collision with his Italian subjects. Six times he was compelled to cross the Alps at the head of great armies, in order to chastise the refractory cities of Lombardy, which were ever ready, on the slightest provocation to throw off their allegiance. In the early periods of his reign, he visited their defection with undue severity; but in his latter days his conduct towards them was characterized by a generous leniency and a politic liberality in advance of his age; and in 1183, he convoked a council at Constance, in which he finally agreed to leave the Lombard cities the right to choose their own municipal rulers, and to conclude treaties and leagues among themselves, although he retained his supremacy over them, together with the power of imposing certain fixed taxes. The difficulty of settling the Italian differences was as usual aggravated in F.'s time by the attitude assumed by the occupants of the papal chair, and one time Italy was distracted by the pretensions of the two rival popes, Alexander III. and Victor IV. who each excommunicated the other, and hurled the anathemas of the church against their several opponents; and it was not till 1176 that F., after his defeat at Legnano, by consenting to acknowledge Urban II., the successor of Alexander III., as the rightful pope, was enabled to turn his attention to Germany. By his energetic measures, he succeeded in thoroughly humbling his troublesome vassal, Henry the Lion, Duke of Brunswick, and thus crushing the Guelphic power in Germany.

F. made Poland tributary to the empire, raised Bohemia to the rank of a kingdom, and the markgraviate of Austria into an independent hereditary duchy. In 1189, F., having settled the affairs of the empire, and proclaimed universal peace in his dominions, resigned the government to his eldest son Henry, and, at the head of 100,000 men, set forth for the Holy Land, accompanied by his second son, Frederick of Swabia, the founder of the order of Teutonic Knights. After gaining two great victories over the Saracens at Philomelum and Iconium, he was drowned (1190) in a river of Syria, while trying to urge his horse across the stream. His remains were rescued by his son, and buried at Tyre. The death of F., which led to the dispersion of the Crusaders before any material advantage had been obtained over the Infidels, excited the deepest grief in Germany, where his memory has always been cherished as that of the best and wisest of his race. F. was a patron of learning, and enacted many admirable laws, some of which are still in force.

FREDERICK II., OF GERMANY, grandson of the former, and son of the Emperor Henry VI., and of Constance, heiress of Sicily, was born in 1194. His mother secured the favor of Pope Innocent III. for her infant son, by conceding many important privileges to the papal chair; and after the civil war which had raged in Germany for eight years between the rival claimants of the throne, Philip of Swabia and Otto IV., was brought to an end by the agency of Innocent, F. succeeded (1212) in obtaining the support of the German electors. On his promising to undertake a crusade, the pope sanctioned his coronation at Aix-la-Chapelle in 1215. Like his grandfather, F. was actuated by an ardent desire for the consolidation of the imperial power in Italy, at the expense of the pontificate, which he wished to reduce to the rank of a mere archiepiscopal dignity. Having secured the nomination of his son Henry to the rank of king of the Romans, and appointed Archbishop Engelbert of Cologne as his vicegerent, he left Germany; and after having been crowned emperor at Rome in 1220, devoted himself to the task of organizing his Italian territories.

He founded the university of Naples, gave encouragement to the medical school of Salerno, invited to his court and patronized men of learning, poets, and artists, and commissioned his chancellor, Petrus de Vineis, to draw up a code of laws, to suit all classes of his German and Italian subjects. F.'s schemes for the union of his vast and widely scattered dominions were, however, frustrated by the refractory conduct of the Lombard cities, and still more by the arrogance of the popes Honorius III. and Gregory IX., who threatened him with excommunication unless he fulfilled his pledge of leading a crusade. Being compelled to depart on this expedition, he made the necessary preparations for its prosecution; but a pestilence having broken out among his troops in the Morea, he returned in haste to Italy, only to be again forced away by papal threats.

This second attempted crusade proved more successful; and in 1228, notwithstanding the machinations of the pope, and the treachery of the Knights Templars, F. extorted a ten years' truce from the Moslem ruler, and forced him to give up Jerusalem and the territory around Joppa and Nazareth. The rest of his life was spent in bringing his rebellious Lombard subjects to subjection, and in counteracting the intrigues of the pope, the rebellion of his eldest son, and the treachery of his friend and minister, the Chancellor Petrus de Vineis, who was suspected of attempting to poison him. F., who died suddenly in 1251, the possessor of seven crowns, was the most accomplished sovereign of the middle ages, for he not only spoke and wrote the six languages common to his subjects, but he was famed for his talents as a minnesinger, and for his skill in all knightly exercises, while he wrote elaborate treatises on natural history and philosophy. His strong sympathies with his Italian mother-land, and his unremitting endeavors to establish a compact and all-supreme empire in Italy, were the causes, not only of his own misfortunes, but of the miseries which he brought upon the German empire, by embroiling him in costly wars abroad, and leading him to neglect the welfare, and sacrifice the interests of his German subjects. See for Frederick I. and Frederick II., Raumer, *Geschichte der Hohenstaufen*; Sismondi, *Italian Republics*, and *Europe in the Middle Ages*; Voigt's *Lombardenbund*; Funk, *Geschichte Kaiser Friedrich II.*

FREDERICK III., OF GERMANY.—Frederick who was F. III. as Emperor of Germany, F. IV. as King of Germany, and F. V. as Duke of Austria, was born in 1415, being the son of Duke Ernst, of the Styrian branch of the house of Hapsburg. At the age of 20, he undertook an expedition to the Holy Land; and on his return, in conjunction with his factious brother, Albert the Prodigious, he assumed the government of his hereditary dominions of the Duchy of Austria, the revenues of which scarcely exceeded 16,000 marks. On the death of the Emperor Albert II., he was unanimously elected as his successor; and two years afterwards, in 1442, he was solemnly crowned at Aix-la-Chapelle; ten years later, he received the imperial crown at the hands of the pope at Rome, and in 1453 secured the archducal title to his family. His reign was a prolonged struggle against domestic intrigues and foreign aggressions. One of his most troublesome opponents was his brother Albert, who refused to give up the provinces which he held until he had received a large sum of money; but notwithstanding these causes of annoyance, and while John Hunyades Corvinus, at the head of a Hungarian army, overran Austria, and laid siege to Vienna, and the usurper Sforza possessed himself of the imperial fief of Milan, on the extinction of the male line of the Visconti, F. remained absorbed in his own private studies, or roused himself only to attempt, by the aid of foreign mercenaries, to recover the crown-lands of which the House of Austria had been deprived.

His pusillanimous subserviency to the papal chair, and his wavering policy, irritated the electors, who at one time cherished the design of deposing him and nominating George Podiebrand, king of Bohemia, to the imperial throne; while it entangled him in quarrels on account of the succession to the Palatinate, and other questions of German policy, and deprived the church in Germany of that independence from the thralldom of the papal chair which it had been the object of the Council of Basel to secure to it. The contempt in which F. was held was made apparent on the death of his ward, Ladislaus, king of Hungary and Bohemia, without children, when, notwithstanding his just pretensions to this inheritance, he was passed over, the people of the former having chosen George Podiebrand as their king, and those of the latter Matthias Corvinus. His brother Albert's death in 1463 seemed him a short reprieve from internal disturbances, and gave him possession of Upper Austria; but he was repeatedly embroiled in quarrels with Podiebrand and Matthias, the latter of whom several times besieged Vienna, and finally dispossessed him of every town of importance in his hereditary domains. In the meanwhile, the Turks were suffered to push their conquests in Europe until they had advanced in 1456 to Hungary, in 1469 to Carniola, and in 1475 to Salzburg, although a vigorous

opposition at the outset would easily have put a definite stop to their encroachments. On the death of Matthias, in 1490, F. recovered Austria, but he was obliged to acknowledge Prince Ladislaus of Bohemia as king of Hungary. This mortification was soon followed by his death, in 1493, after an inglorious reign of 53 years, which did nothing to advance the prosperity or progress of the empire, although the times were propitious to both. But although F. neglected the interests and duties of the imperial crown to indulge in the pursuit of his favorite studies in alchemy, astronomy, and botany, he never lost an opportunity of promoting the aggrandizement of his own family, which he very materially secured by marrying his son and successor, Maximilian, to Mary, the rich heiress of Charles the Bold of Burgundy. F. was temperate, devout, parsimonious, scrupulous about trifles, simple in his habits, pacific in his disposition, and naturally averse to exertion or excitement. From his time, the imperial dignity continued almost hereditary in the House of Austria, which has perpetuated the use of his favorite device, A. E. I. O. U. *Austrie Est Imperare Orbi Universo*. See *Æneas Sylvius, Historia; Coxe, House of Austria*.

FREDERICK V., PRINCE PALATINE.—Frederick V., Electoral Prince Palatine, was born in 1596, succeeded to the Palatinate in 1619, was king of Bohemia from 1619 to 1620, and died in 1632. He married, in 1613, Elizabeth, the daughter of James VI. of Scotland and I. of England, through whose ambitious counsels he was induced to take a prominent part in the proceedings of the union of the Protestant princes of Germany, and finally, although against his own inclinations, to accept the title of king of Bohemia. His complete defeat at the battle of Prague terminated his short-lived enjoyment of the regal crown, of which he retained no other memorial but the mocking title of 'The Winter King.'

Ridicule and contumely followed him wherever he went, and the rest of his life was spent in exile under the ban of the empire, and with no resources beyond those which he could obtain from the generosity of his friends. In 1623, he was declared to have forfeited his electoral title and his dominions in the Palatinate, which were conferred upon his cousin, Maximilian of Bavaria, the head of the Catholic league.

FREDERICK I., OF DENMARK, was born in 1473, and died in 1533. During the disturbed reign of his nephew, Christian II., he behaved with so much circumspection, that the choice of the nation fell upon him when the king was deposed, and he was raised to the throne in 1523. He showed great cruelty to his unfortunate relative, whom he detained in close captivity; but he was a politic ruler. In 1527 he embraced the Lutheran faith, which he established in his dominions by the most arbitrary measures.

FREDERICK III., OF DENMARK, the son of Christian IV., was born in 1609, succeeded to the throne in 1648, and died in 1670. The wars of his father's reign had brought the country to a state of great embarrassment; and notwithstanding all his efforts to maintain peace, F. was continually embroiled in the quarrels of other nations, and during his reign Copenhagen was twice besieged by the Swedes under their warlike king, Charles Gustavus; nor was peace re-established till after the death of Charles. The reign of F. III. was rendered memorable by the change effected in the constitution, which, after having been in some degree elective, was at once changed into a hereditary and absolute monarchy by the voluntary act of the commons and clergy, who, from abhorrence of the nobility, surrendered to the crown the liberties and prerogative which they had hitherto enjoyed, and made the sovereign absolute and irresponsible.

FREDERICK V., OF DENMARK, the son and successor of Christian VI., was born in 1723, ascended the throne in 1746, and died in 1766, leaving the reputation of having been one of the best and wisest monarchs of his time. Denmark owed to him the increase of her national wealth, and the establishment of various branches of commerce and manufacture. F. established a Greenland Company, opened the American colonial trade to all his subjects, founded the military academy of Sorø, in Denmark, and caused schools to be opened at Bergen and Tromsø, in Norway, for the instruction of the Laplanders. He established a academy of painting and sculpture at Copenhagen, and sent a number of learned men—among whom was Niebuhr, the father of the historian—to travel and make explorations in the East.

FREDERICK VI., OF DENMARK, the son of Christian VII. and Caroline Matilda of England, was born 1768, and assumed the regency of the kingdom in 1784, on account of the insanity of his father, on his death, in 1808, he ascended the throne. In this reign, feudal serfdom was abolished, monopolies abrogated, the criminal code amended, and the slave-trade prohibited earlier than in any other country.

In 1800, Denmark joined the maritime confederation formed between Russia, Sweden, and Prussia, which led to retaliation on the part of England, to the seizure by that power of all Danish

vessels in British ports, and to the despatch of a powerful fleet, under Sir Hyde Parker and Nelson, to give efficacy to the peremptory demand that the regent should withdraw from the convention. His refusal to accede to this demand was followed by a fierce naval engagement, in which the Danish fleet was almost wholly destroyed. A peace was concluded on the regent's withdrawal from the confederation; but in consequence of his persisting to maintain an attitude of neutrality, instead of combining with Great Britain against Napoleon, the war was renewed in 1807 by the appearance, before Copenhagen, of a British fleet, bearing envoys, who summoned F. to enter into an alliance with England, and to surrender his fleet and arsenals, and the castle of Cronborg, commanding the sound. On his refusal, Copenhagen was bombarded for three days, the arsenals and docks destroyed, and all the shipping disabled, sunk, or carried to England. This blow paralyzed the national resources, and it required the exercise of much discretion on the part of the government, and great endurance on that of the people, to prevent the irremediable ruin of the country. Smarting under the treatment which he had experienced from the English, the Danish monarch became the ally of Napoleon, and suffered proportionally after the overthrow of his empire. In 1814, Norway was taken by the allies from Denmark, and given to Sweden. The state became bankrupt, and many years passed before order could be restored to the finances. Notwithstanding his autocratic tendencies, F. so far yielded to the movements of the times as to give his subjects, in 1831, a representative council and a liberal constitution. He died December 3, 1839.

FREDERICK VII., OF DENMARK, the late king of Denmark, was born in 1808, and succeeded his father, Christian VIII., in 1848. The principal events of his reign were the wars and diplomatic negotiations arising out of the revolt of the duchies of Holstein and Slesvig (q. v.), and the vexed question of the succession to Denmark Proper and the duchies on the death of the king and of his uncle, the heir-presumptive, both of whom were childless. Notwithstanding the heavy expenses of the war, the material prosperity of the country increased during F.'s reign. He died 15th Nov. 1863.

FREDERICK-CHARLES, a Prussian prince, son of Prince Charles (brother of King William), was born at Berlin, 20th March 1828. In his early youth, he manifested a great liking for warlike occupations; and the first Slesvig-Holstein war (1849) saw him in the field as captain, and not without honor to himself; in the campaign in Baden also he gathered laurels and honorable wounds; and in the second Slesvig-Holstein war his name became famous through the storm of the Düppel entrenchments. But his chief title to fame rests on the part he played in the campaign of 1866 against Austria, where he commanded one of the invading armies, and where his able generalship contributed not a little to the final success of the war.

He has indeed been blamed for excess of caution in advancing through Bohemia to the rendezvous at Gitschin, where his more prompt appearance, it is said, would have saved the Silesian army from the danger of serious disaster which it encountered in passing the defiles; but it may, in fairness, be assumed that the caution was necessary until the contrary is proved. Besides his services in the reorganization of the cavalry, he has written several military works of great merit. He commanded the second German army in the Franco-German war, and the investing forces when Metz capitulated Oct. 27, 1870; and next day was made field-marshal by King William, now Emperor of Germany. He was married to Marie Anna, Princess of Anhalt, in 1854. In March 1879 his third daughter, Louise Margaret, was married to the Duke of Connaught.

FREDERICK-WILLIAM, DUKE OF BRUNSWICK, born in 1771, entered the Prussian service at an early age, and was actively engaged with the army during the war with France in 1792, and again in 1806, and was taken prisoner with Blücher at Leipsic. On the death of his father and eldest brother, he would have succeeded to the dukedom, as his other brothers were incapacitated by disease for reigning, had not Napoleon put a veto on his accession to power. Being resolved to take part in the war against the French, he raised a free corps in Bohemia, and threw himself into Saxony, which he was, however, speedily compelled to evacuate. After the total defeat of the Austrians in 1809, the duke determined to leave Germany; and with his corps of 700 'black hussars,' and 800 infantry, he began his masterly retreat. After various skirmishes, in one of which he defeated the Westphalian commander Wellingerode and a picked detachment of troops, he reached Brunswick, in the neighborhood of which he gained a victory at Oelpe over 4000 Westphalians, commanded by General Renpel. He next crossed the Weser, and having reached Elsteth, and taken possession of a sufficient number of vessels and seamen, he embarked his troops; and finally, after stopping at Heligoland, landed in England with his men in August 1809. He was received with enthusiasm; and having entered the Eng-

fish service with his men, subsequently took part in the Peninsular war, where he served with distinction, receiving from the British government an allowance of £6000 a year, which he retained till his return to his own dominions in 1813. Although no prince could be more earnestly bent on securing the welfare of his subjects, his efforts failed utterly from the untimely and injudicious nature of the reforms he endeavored to effect, while the magnitude of his military establishments, which were quite unsuited to the limited extent of his territories, excited the ill-will of his people. He joined the allied army with his hussars after the return of Napoleon from Elba, and fell gloriously while leading on his men at Quatre Bras, on the 16th of June 1815.

FREDERICK-WILLIAM, ELECTOR OF BRANDENBURG, commonly called 'the Great Elector,' was born in 1620, succeeded to the electorate in 1640, and died in 1688. On his accession, he found an empty exchequer, the towns and cities depopulated, and the whole electorate devastated by the ravages of the Swedish and Imperialist armies during the Thirty Years' War, which was not yet concluded; while a portion of his inheritance had even been confiscated by the Swedes. His first acts were to regulate the finances, and to conclude a treaty of neutrality with Sweden, which left him at leisure to devote himself to the organization of his army, and the re-peopling of the deserted towns and villages by means of immigration. By the treaty of Westphalia, through which he lost several important places, he recovered the eastern portions of Pomerania, Hohenstein, the bishoprics of Halberstadt, Minden, and Kamin, as lay-principalities, and the reversion of the archbishopric of Magdeburg. In the course of ten years he had, by the help of his generals, Defflinger, Schomberg, and Kunenbergh, created an army of 25,000 men, organized on the Swedish model; and having been constrained to enter into an alliance with Charles X., he co-operated with him in the taking of Warsaw, which was effected at the cost of a most sanguinary engagement in 1656. In return for this co-operation, F.-W. secured the emancipation of his Prussian duchy from its former dependence on Poland. The aggressions of Louis XIV. on the Rhenish frontier alarmed the elector, who induced the emperor, the king of Denmark, and the Elector of Hesse-Cassel, to enter into a league against France. The result was unfavorable to the cause of the German princes, and F.-W. was obliged to content himself with making highly disadvantageous terms. The war was soon renewed, and Brandenburg was again a prey to the incursions of the Swedes, who at the instigation of Louis, advanced upon Berlin, laying waste everything on their march. The elector, who had taken up his winter-quarters in Franconia, hurried across the Elbe at the head of his cavalry, and having signally defeated the Swedes, drove them from his dominions. If the emperor had been true to his word, and supported him, F.-W. might have made head against the French; but being forsaken by the other German princes, and his dominions overrun by the troops of Louis, he was obliged to agree to the treaty of St. Germain, by which he restored all his conquests to the Swedes, in return for the withdrawal of the French army, and the payment to him of an indemnity of 300,000 crowns. From this time forth, F.-W. devoted himself to the task of consolidating the prosperity of his dominions. During his reign, he more than tripled the area of his territories, and by his generous reception of 20,000 French Protestants after the revocation of the Edict of Nantes, and the encouragement which he afforded to the immigration of Dutchmen and other foreigners, he augmented the population of his states, and introduced numerous industrial arts among his subjects. He founded the university at Duisburg, and the royal library at Berlin, and reorganized the universities of Frankfurt-on-the-Oder, and Königsberg, opened canals, established a system of posts, and greatly enlarged and beautified Berlin. He left a well-filled exchequer and a highly organized army. See Orlich, *Gesch. des Preuss. Staats im 17. Jahrh.*

FREDERICK III., ELECTOR OF BRANDENBURG, son and successor of the former, and the first king of Prussia, was born in 1657, and succeeded to the electorate of Brandenburg in 1688. He exhibited the same zeal as his father for the aggrandizement and amelioration of his dominions; but he was distinguished from him by his admiration of Louis XIV., whose pomp and luxurious display he imitated at his own court. He supported William of Orange in his attempt on England, and gave him a subsidy of 6000 men, which, under the command of Marshal Schomberg, contributed to gain the victory at the Boyne which decided the fate of James II. F. was always ready to lend troops and money to his allies; he sent 6000 of his best men to aid the Imperialists against the Turks; and although he met with the same ingratitude as his father, he succeeded, by treaties, exchanges, and purchases, in very considerably extending his territories; and after many years' negotiations, he induced the emperor to agree to the 'Crown Treaty,' by which, in return for permission to assume the title of King of Prussia, he bound himself to furnish certain contingents of men and money to the Imperial government. As soon as this treaty had been signed, F. hastened in mid-winter

with all his family and court to Königsberg, where, on the 18th January 1701, he placed the crown on his own head. He died February 25, 1713. F. did much to embellish Berlin, where he founded the Royal Academy of Sciences, and the Academy of Painting and Sculpture, erected several churches, and laid out numerous streets. He established a court of appeal at Berlin, built the palace of Charlottenburg, and founded the university at Halle; but his actions were generally influenced by a love of display; and his vanity, together with his neglect of those who had served him, made him personally unpopular, although his patriotic love of Germany redeemed, in the eyes of his countrymen, many of his bad points.

FREDERICK-WILLIAM I., OF PRUSSIA, born in 1688, was in almost every particular the opposite of his father Frederick I. He was simple, and almost penurious in his habits, attentive to business, passionately fond of military exercises, but averse to mental cultivation, and fond of the society of the low and illiterate, while he carried to the utmost his ideas of arbitrary power and the divine right of kings. The public events of his reign were of little importance, although he was continually implicated in foreign wars, and he supported the cause of Stanislaus of Poland, and assisted Austria in her contests with France. He died in 1740. By his economy and reforms in the finances, he was able to indulge his taste for the organization of military forces, while his childish love of tall soldiers induced him to connive at the most flagrant outrages both at home and abroad for kidnapping tall men and forcing them into his service: the result of this system was, that he left at his death a well-drilled army of 70,000 soldiers, of whom a large proportion were men of gigantic stature. What was of more consequence to his son and successor was, that his exchequer contained 9,000,000 thalers, and that his kingdom had attained an area of more than 45,000 square miles, and a population of upwards of 2,240,000. See Morgenstern, *Ueber Friedrich Wilhelm I.* (Braunsch. 1793); F. Förster, *Gesch. Friedrich-Wilhelm's I.* (Pots. 1835); Carlyle, *Hist. of Frederick II., called Frederick the Great.*

FREDERICK II., OF PRUSSIA, surnamed 'THE GREAT,' was the son of Frederick-William I. and the Princess Sophia-Dorothea, daughter of George I. of Great Britain, and was born in 1712. His early years were spent under the restraints of an irksome military training, and a rigid system of education. His impatience under this discipline, his taste for music and French literature, and his devotion to his mother, gave rise to dissensions between father and son, and resulted in an attempt on the part of F. to escape to the court of his uncle, George II. of England. Being seized in the act, his conduct was visited with still greater severity, and he himself was kept in close confinement, while his friend and confidant, Lieutenant Katt, was executed in his sight, after having been barbarously ill-treated by the king. According to some reports, the prince's life would have been sacrificed to the fury of his father, had not the kings of Sweden and Poland interceded in his favor. Having humbly sued for pardon, he was liberated, and allowed to retire to Rappin, which, with the town of Rheinsberg, was bestowed upon him in 1734. Here he continued to reside till the king's death, surrounded by men of learning, and in correspondence with Voltaire, whom he especially admired, and other philosophers; but on his accession to the throne in 1740, he laid aside these peaceful pursuits, and at once gave evidence of his talents as a legislator, and his determination to take an active share in the political and warlike movements of the age. His first military exploit was to gain a victory at Mollwitz over the Austrians, in 1741, which nearly decided the fate of Silesia, and secured to Prussia the alliance of France and Bohemia. Another victory over the Empress Maria Theresa's troops made him master of Upper and Lower Silesia, and closed the first Silesian war. The second Silesian war, which ended in 1745, from which F. retired with augmented territories and the reputation of being one of the first commanders of the age, was followed by a peace of eleven years, which he devoted to the improvement of the various departments of government, and of the nation generally, to the organization of his army, and the indulgence of his literary tastes. The third Silesian war, or 'The Seven Years' War,' was begun in 1756 by the invasion of Saxony—a step to which F. was driven by the fear that he was to be deprived of Silesia by the allied confederation of France, Austria, Saxony, and Russia. This contest, which was one of the most remarkable of modern times, secured to F. a decided influence in the affairs of Europe generally, as the natural result of the pre-eminent genius which he had shown both under defeat and victory; but although this war crippled the powers of all engaged in it, it left the balance of European politics unchanged. It required all the skill and inventive genius of F. to repair the evils which his country had suffered by the war. In 1772, he shared in the partition of Poland, and obtained as his portion all Polish Prussia and a part of Great Poland; and by the treaty of Teschen, in 1779, Austria was obliged to consent to the union of the Franconian provinces with Prussia, and he was thus

enabled to leave to his nephew and successor a powerful and well-organized kingdom, one-half larger in area than it had been at his own accession, with a full treasury, and an army of 200,000 men.

He died at the château of Sans Souci, August 17, 1786. Frederick the Great is said to have 'inherited all his father's excellences and none of his defects.' His courage, fertility of resource, and indomitable resolution, cannot be too highly praised. Not the least wonderful of his achievements was his contriving to carry on his bloody campaigns without incurring a penny of debt. A true spirit of self-sacrifice—though not, perhaps, for the highest ends—was in him. Never was king more liberal towards his subjects. In Silesia, where war had nearly ruined the inhabitants, he once remitted the taxes for six months, and in Pomerania and New Brandenburg for two years, while his government was carried on with rigid economy, such as Europe had never before witnessed. But not only was his government economical, it was essentially just. Religious persecution was unknown, civil order everywhere prevailed; property was secure, and the press was free. On the other hand, F.'s faults were far from being few. Education had made him French in all his ideas and prejudices; and in those days, to be French was to be sceptical. He was utterly unconscious of the grand intellectual and spiritual life that was about to spring up in Germany, and to make it again the guiding-star of Europe, as it had been in the days of Luther. He was, in fact, almost ignorant of his native language, which, moreover, he despised as semi-barbaric; though before his death Goethe had published his *Götz von Berlichingen*, *Sorrows of Werther*, *Iphigenia in Tauris*, and many of his finest lyrics; while Kant, besides a variety of lesser works, had also given to the world his master-piece, the *Critique of Pure Reason*. The new literature was essentially one of belief and aspiration, and therefore alien to the tendencies of the royal disciple of Voltaire, who had learned from his master to cherish at once contempt and suspicion of his fellow-creatures. This disagreeable feature of his character increased with years. He declared the citizen class to be destitute alike of ability and honor, and relied not on the love of the nation, but on his army and purse. F. was a very voluminous writer. Of his numerous works, all of which are written in French, his *Mémoires pour servir à l'Histoire de Brandebourg*, and *Histoire de la Guerre de Sept Ans*, exhibit perhaps the greatest powers of description, but all evince talent of no common order. The Academy of Berlin, by the direction of Frederick-William IV., brought out a fine edition of his collected works in octavo and quarto, 1846—1851. Frederick left no children, and was succeeded by his nephew, Frederick-William II. See Carlyle, *History of Frederick II.*; Macaulay's *Essay*; and the lives by Dolm, Preuss, Förster, Kugler, Droysen, Klopp, Pelletan (1878).

FREDERICK-WILLIAM II., OF PRUSSIA, was born in 1744, and died in 1797. After a prolonged estrangement between his uncle and himself, he regained the good-will of the king by his valor in the war of the Bavarian succession in 1778; but although he succeeded to a well-consolidated power and an overflowing treasury, he had not the capacity to maintain his favorable position. Futile or hastily undertaken wars wasted his resources; so that at his death, instead of the overplus of 70,000,000 thalers that had been bequeathed to him, the state was hampered with a debt of 22,000,000.

His predilection for unworthy favorites, the establishment of a strict censorship of the press, and the introduction of stringent ecclesiastic enactments, alienated the affections of the people from him, although his natural mildness of disposition had excited the sanguine hopes of the nation on his accession. F.-W. shared in the second partition of Poland in 1793, and thus gained a considerable addition to his kingdom, which, by purchase, inheritance, and other means, was augmented during his reign by the acquisition of more than 46,000 square miles of territory, and 2½ millions of inhabitants. The chief internal improvements in this reign were the introduction of a new code of laws, and a less onerous mode of raising the taxes.

FREDERICK-WILLIAM III., OF PRUSSIA, the son of Frederick-William II., was born in 1770. He early took part in the administration, and, on his accession in 1797, he at once dismissed the unworthy favorites of the preceding reign, and accompanied by his beautiful young queen, Louisa of Mecklenburg-Strelitz, made a tour of inspection through the numerous provinces of his kingdom, with a view of investigating their condition, and contributing to their local and general improvement. But although F.-W. was well intentioned, and in his moral and domestic relations his conduct was exemplary, he lacked the dignity and force of will to cope with the difficulties of his position. By his efforts to maintain an attitude of neutrality in the great European struggle that had been excited by the wars and victories of the French, he awakened the distrust of all the great anti-Gallician powers of Europe, and disappointed the petty German princes, who had looked upon Prussia as their protectress against foreign

encroachments. Napoleon's promises of support and friendly intentions soon changed this neutrality to an alliance with France, and for some time Prussia persevered in her dishonorable and self-seeking policy, which was rewarded by the acquisition of Hildesheim, Paderborn, and Münster, which added nearly 4000 square miles of territory, and half a million of inhabitants to the kingdom; but at length the repeated and systematic insults of Napoleon, who despised F.-W. while he professed to treat him as a friend, roused the spirit of the nation, and the king saw himself obliged, in 1805, to agree to a convention with Russia, the real object of which was to drive Napoleon out of Germany. Again the treachery of Prussia led her to make a new treaty with France, by which she consented to receive the electorate of Hanover, and thus involved herself in a war with England. The insults of Napoleon were redoubled after this fresh proof of F.-W.'s indecision. The Prussian nation, headed by the queen, now called loudly for war, and at the close of 1806, the king yielded to these appeals. Hostilities began without further delay; but the defeat of the Prussians at Jena, Eylau, and Friedland, compelled their unfortunate monarch to sue for peace. The Prussian army was annihilated, and the whole of the kingdom, with the exception of a few fortified places, remained in the power of the French.

By the intervention of the Emperor Alexander of Russia, a peace was concluded, known as the Treaty of Tilsit, by which F.-W. lost the greater part of his realm, and was deprived of all but the semblance of royalty; but although for the next five years he was a mere tool in the hands of Napoleon, who seized every opportunity of humbling and irritating him, his spirit was not subdued, and his unremitting efforts at this period of his life to reorganize his enfeebled government by self-sacrifices of every kind, endeared him greatly to his people. The disastrous termination of Napoleon's Russian campaign was the turning point in the fortunes of Prussia; for although the French emperor was victorious over the Prussians and Russians in the battles of Lützen and Bautzen, which were fought soon after the declaration of war which F.-W. had made against France, to the great joy of his people, in 1813, the allies were soon able to renew hostilities, which were carried on with signal success, until they finally culminated in the great battle of Leipzig, in which the Prussians, under their general, Blücher, earned the greatest share of glory. The Peace of Vienna restored to Prussia almost all her former possessions, while the part taken by the Prussian army under Blücher in gaining the victory of Waterloo, by which Napoleon's power was finally broken, raised the kingdom from its abasement. From that time, F.-W. devoted himself to the improvement of his exhausted states; but although before the French revolution of 1830 Prussia had recovered her old position in regard to material prosperity at home and political consideration abroad, the king adhered too strictly to the old German ideas of absolutism, to grant his people more than the smallest possible amount of political liberty. He had indeed promised to establish a representative constitution for the whole kingdom, but this promise he wholly repudiated when reminded of it, and merely established the *Landstände*, or Provincial Estates, a local institution, devoid of all effective power. His support of the Russian government in its sanguinary methods of crushing revolutionary tendencies in Poland, showed his absolute tendencies, and his dread of liberal principles. F.-W. was more than once embroiled with the pope, on account of his violation of the concordat. He concluded the great German commercial league known as the *Zollverein* (see GERMANY), which organized the German customs and duties in accordance with one uniform system. He died in 1840.

FREDERICK-WILLIAM IV., OF PRUSSIA, son of the foregoing, was born October 15, 1795. He had been carefully educated, was fond of the society of learned men, and was a liberal patron of art and literature. He exhibited much of his father's vacillation and instability of purpose; and although he began his reign (June 7, 1840) by granting minor reforms, and promising radical changes of a liberal character, he always, on one plea or another, evaded the fulfilment of these pledges. He was possessed by high but vague ideas of 'the Christian state,' and showed through life a strong tendency to mystic pietism. The one idea to which he adhered with constancy was that of a union of all Germany into one great body, of which he offered himself to be the guide and head. He encouraged the duchies of Holstein and Slesvig in their insurrectionary movement, and sent troops to assist them against Denmark; but he soon abandoned their cause, and being displeased with the revolutionary character of the Frankfurt Diet, refused to accept the imperial crown which it offered him.

The conspiracies in Prussian Poland were suppressed with much rigor; and the popular movement which followed the French revolution of 1848, was at first met by the king with resolute opposition; but when the people persisted in demanding the removal of the troops from the capital, and enforced their demand by storming the arsenal, and seizing on the palace of the Prince of

Prussia (the present king), who was at the time especially obnoxious to the liberals, he was obliged to comply with their wishes. Constituent assemblies were convoked, only to be dissolved when the king recovered his former security of power, and new constitutions were framed and sworn to, and finally modified or withdrawn. After the complete termination of the revolution in Germany, the revolutionary members of the Assembly of 1848 were prosecuted, and treated with severity, the obnoxious 'pietistic' party and the nobility were reinstated in their former influence at court, and the freedom of the press and of religious and political opinion, was strictly circumscribed. The life of the king was twice attempted; first in 1847 by a dismissed burgo-master, named Tschetch; and secondly, in 1850, by an insane discharged soldier of the name of Sefeloge. In 1857, F.-W. was seized with remittent attacks of insanity; and in 1858 he resigned the management of public affairs to his brother and next heir, who acted as regent of the kingdom till his own accession, in 1860, as William I. F.-W. died in 1861.

FREDERICK CITY, a city of Maryland, U.S., 44 miles north-west of Washington, 65 miles west of Baltimore, on a branch of the Baltimore and Ohio Railroad; a handsome town with manufactures of iron, wool, leather, paper, flour, and tobacco. Frederick College was founded by the state in 1797; here are also a seminary of females, a Jesuit establishment and a nunnery, and a deaf and dumb institute. Pop. (1870) 8526; (1880) 8659.

FREDERICKSBURG, a city of Virginia, U.S., is on the right bank of the river Rappahannock, 110 miles from Chesapeake Bay, 65 miles north of Richmond. Here are the county buildings, several churches and public schools, an orphan asylum, and extensive manufactures of flour and tobacco. Pop. (1880) 5010. On December 13, 1862, it was the scene of a battle between the Federal army, commanded by General Burnside, and the Confederate army under General Lee, in which the former was repulsed, and driven back across the river with a loss of 12,321, while the Confederates, strongly posted on the hills south of the city, suffered but trifling damage; but the city itself was nearly destroyed.

FREDERICK-WILLIAM, Crown-prince of the German Empire and of Prussia, only son of William I. (q. v.), king of Prussia and now German emperor, was born 18th October 1831. His earnest character and eminent talents were early developed under the care of excellent masters, among others of Ernest Curtius (q. v.), who also accompanied him to the university of Bonn, where the prince was matriculated in the law faculty.

After the completion of his education, the prince visited several foreign countries, among others, England, where it seems he became attached to the Princess Royal, eldest daughter of Queen Victoria, and was married to her on the 25th January 1858, with the highest approbation of both nations. Of the issue of this union, there are now living two sons (the eldest Frederick-William, born 27th January 1859), and four daughters. Since his father ascended the throne, the Crown Prince has taken part in the more important affairs of state. He served in the Danish campaign in a subordinate capacity; nevertheless, he gave sufficient proofs of his great ability, to cause the king to intrust to him an important (according to some the most important) task in the war with Austria in 1866, namely, the command of the left Prussian wing operating in and from Silesia. How ably the prince played his part at Königgrätz is well-known. In the Franco-German war, 1870—1871, he acted a very conspicuous part as commander of the troops of Bavaria, Würtemberg, and Baden. He was present at Sedan, August 1870; and was made a field-marshal two months after, by his father. F.-W. is heir-presumptive to the imperial crown of Germany, as well as the throne of Prussia. During the Emperor's illness caused by an assassin's shot in 1878, his public functions were performed by the Crown-Prince.

FREDERICTON, capital of the province of New Brunswick, Canada, stands on the St. John River, 56 m. to the N.W. of the port of St. John. Pop. (1881) 6218. Besides other public buildings, F. contains the university of New Brunswick, which is well endowed, and has a good staff of professors.

FREDERIKSHALD, a fortified seaport of Norway, in the department (amt) of Smalenen, stands on an inlet called Swinesund, near the Swedish border, about 60 miles S.S.E. of Christiania. It is beautifully situated, and is a neat, well-built town, with several handsome edifices. Its harbor is excellent; in it the largest vessels may be safely moored. F. largely exports deals and lobsters. Pop. 9956. To the S.E. of the town stands the fortress of Frederiksteen, on a perpendicular rock 400 feet high. This fortress though often assaulted, has never yet been taken. While laying siege to Frederiksteen, Charles XII. of Sweden was killed, 1718; in commemoration of which event an obelisk was raised, in 1814, upon the spot where he fell.

FREE BENCH (*Francus Bancus*). By custom of certain manors in England, a widow was entitled to dower out of the

lands which were held by her husband in Socage (q. v.). In some places, the widow had the whole, or the half; and the like *dum sola et casta vixerit* (Co. Litt. 110, b.). This right is called *francus bancus*, to distinguish it from other dowers, for that it cometh freely, without any act of the husband's or assignment of the heir (Co. Litt. 94, b.). See **DOWER**. A widow who has forfeited her free bench is, by the custom of some manors, permitted to recover her right. At East and West Enborne, in the county of Berks, and also in the manor of Chadleworth, in the same county and at Torr, in Devon, if the widow commit incontinency, she forfeits her estate; yet if she will come into the court of the manor riding backward on a blackram, with his tail in her hand, and will repeat certain verses (more remarkable for their plainness than their delicacy), the steward is bound by the custom to admit her to her free bench. (Cowel's *Interpreter*, ed. 1727, fol.).

FREE CHURCH OF SCOTLAND, the name assumed by those who at the 'Disruption' of the Established Church of Scotland, in 1843, withdrew from connection with the state, and formed themselves into a distinct religious community, at the same time claiming to represent the historic church of Scotland, as maintaining the principles for which it has contended since the Reformation.

(It is proper to state that, in accordance with a method adopted in other cases also in this work, the present article is written by a member of the church to which it relates, and is an attempt to exhibit the view of its principles and position generally taken by those within its own pale.)

There is no difference between the F. C. of S. and the Established Church in the standards which they receive; and all the laws of the church existing and in force prior to the Disruption, are acknowledged as still binding in the one as much as in the other, except in so far as they may since have been repealed. The same Presbyterian constitution subsists in both churches, with the same classes of office-bearers and gradations of church-courts. The F. C. indeed, professes to maintain this constitution and church-government in a perfection impossible in the present circumstances of the Established Church, because of acts of parliament by which the Established Church is trammelled, and interventions of civil authority to which it is liable. And the whole difference between the F. C. and the Established Church relates to the consent and submission of the Established Church to this control of the civil power in things which the F. C. regards as belonging not to the province of civil government, but to the church of Christ and to its office-bearers and courts, as deriving authority from Him; so that the controversy is often described as respecting the *Headship of Christ* or the *Kingdom of Christ*. It is to be borne in mind, however, that the doctrine of the headship of Christ over his church, as set forth in the Westminster standards, is fully professed both by the Established Church and by the F. C. of Scotland; the only question between them is, whether or not the existing relations of the Established Church of Scotland to the state are consistent with the due maintenance and practical exhibition of this doctrine. And the question does not directly relate to *Voluntaryism* (q. v.). Those who constituted the F. C. of S. in 1843, firmly believed that the church might be connected with the state, and receive countenance and support from it, to the advantage of both; whilst they maintained that there must not, for the sake of any apparent benefits flowing from such connection, be any sacrifice of the independence or self-government of the church, as the kingdom of Christ, deriving its existence, organization, and laws from Him. Nor has any change of opinion on this subject been manifested.

The Westminster Confession of Faith asserts 'that there is no other head of the church but the Lord Jesus Christ; and that 'the Lord Jesus, as the King and Head of his church, hath therein appointed a government in the hand of church-officers, distinct from the civil magistrate;' it ascribes to these church officers the right of meeting in 'synods or councils,' which it affirms to be 'an ordinance of God;' and represents the exercise of church discipline as intrusted to them as well as the ministry of the word and sacraments. It ascribes to the civil magistrate much power and many duties concerning things spiritual, but no power in or over these things themselves. And all this was equally the doctrine of the Church of Scotland before the Westminster Confession was compiled. The support which, in many parts of Europe, princes gave to the cause of the Reformation, and the circumstance that states as well as churches were shaking off the fetters of Rome, led in many cases to a confounding of the civil and the spiritual. The Church of Scotland accomplished its emancipation from Rome not with the co-operation of the civil power, but in spite of its resistance; and after the Reformation, the Scottish Reformers and their successors were compelled to a closer study of their principles, by the continued attempts of the civil rulers to assume authority over all the internal affairs of the church. But amidst their struggles, the Presbyterians of Scotland so far prevailed as to obtain at different times important acts of parliament in recognition of their principles, and 'ratification of the liberty of the true kirk;'

and finally, after the Revolution of 1688, an act ratifying the Westminster Confession of Faith itself, and incorporating with the statute law of the realm all its statements concerning the province of church-judicatories and that of the civil magistrate, and the bounds of their respective powers.

The rights and privileges of the Presbyterian Church of Scotland guaranteed by the Revolution settlement, were expressly secured by the Treaty of Union, and jealously reserved from the power of the British parliament; yet within five years afterwards, when Jacobite councils prevailed in the court of Queen Anne, an act was passed for the restoration of patronage in Scotland, with the design of advancing the Jacobite interest by rendering ministers more dependent on the aristocracy, and less strenuous advocates of the most liberal principles then known. This soon became the cause of strife within the Church of Scotland, and of separation from it; effects which have continually increased to the present day. How the church at first earnestly protested against this act; how this protest gradually became formal, and was at last relinquished; how the church-courts themselves became most active in carrying out the settlement of presentees, notwithstanding all opposition of congregations, are points to which it is enough here to allude.

It is important, however, to observe that in all the enforcement of the rights given to patrons by the act of 1712, during the 18th c., and considerable part of the 19th, no direct invasion of the ecclesiastical province took place on the part of civil courts or of the civil power; the presentation by the patron was regarded as conveying a civil right at most to the benefice or emoluments only, whilst the church-courts proceeded without restraint in the induction of ministers; and in a few instances it happened that the benefice and the pastoral office were disconnected by the opposite decisions of the civil and ecclesiastical courts. And even the 'forced settlements,' in which the fullest effect was given by the church-courts to the will of patrons, were accomplished according to the ancient form, upon the *call* of the parishioners, inviting the presentee to be their minister, although the *call* was a mere form—in the words of Dr. Chalmers, 'the expressed consent of a few, and these often the mere dribble of a parish.'

When the 'Moderate' party, long dominant in the General Assembly of the Church of Scotland, became again the minority in 1834, the accession of the 'Evangelical' party to power was at once signalized by an attempt to restore the *call* to efficacy. This was done by the famous *Veto Law*, by which it was declared 'that it is a fundamental law of this church that no pastor shall be intruded on any congregation contrary to the will of the people,' and enacted, in order to give effect to this principle, that a solemn dissent of a majority of male heads of families, members of the vacant congregation, and in full communion with the church, shall be deemed sufficient ground for the rejection of the presentee. The Veto Law thus determined rather how strong an expression of dissent by the parishioners should be requisite to invalidate a call, than how strong an expression of assent should be requisite to give it validity; a circumstance which was afterwards much turned to account in controversy; as if the *veto* were a new and unconstitutional principle introduced; although it was certainly adopted as the least extreme mode of giving effect to the old principle which the law declared.

The same General Assembly by which the Veto Act was passed, is memorable for the assertion of the constitutional principles and inherent powers of the church in another important particular, the admission of the ministers of 'chapels of ease' to the same ecclesiastical status with the ministers of endowed parishes, in consequence of which they became members of church-courts, and had districts assigned to them *quoad sacra*, with the full parochial organization.

The Veto Act was soon the subject of litigation in the Court of Session. A conflict arose which in various forms agitated the whole of Scotland, and which, ere long, related as much to the status of chapel ministers as to the rights of presentees to parishes; and indeed involved the whole question of the relations of civil and ecclesiastical powers, at least as far as the Established Church was concerned. The first case carried into the civil court was that of a presentation to Auchterarder, in which the call to the presentee was signed by only two parishioners, whilst almost all who were entitled to do so according to the Veto Act, came forward to declare their dissent. The decision of the Court of Session, which, upon an appeal, was affirmed by the House of Lords, was to the effect, that the rejection of the presentee on the ground of this dissent was illegal; the opinions of the judges in the Scottish court were indeed divided; but those in accordance with which the judgment was pronounced, asserted the right of the civil courts to review and control all proceedings of church-courts, a power which it was speedily attempted to put forth in other cases, to the extent of requiring presbyteries to proceed to the settlement of qualified presentees without respect to the opposition of congregations; interdicting the admission of ministers to pastoral charges even when no question of emoluments was involved; interdicting the *quoad*

sacra division of parishes or any innovation on the existing state of a parish as to pastoral superintendence and the jurisdiction and discipline of the kirk-session; interdicting church-courts from pronouncing ecclesiastical censures, and suspending or revoking them when pronounced; interdicting ministers from preaching the gospel and from administering the sacraments within certain parishes; determining who should and who should not be deemed entitled to sit and vote in General Assemblies and other courts of the church; and other such things, wholly subversive of the independence of the church, and reducing it, if acquiesced in, to the condition of 'a creature of the state.' They were not, however, acquiesced in; and although in one instance, ministers were brought to the bar of the Court of Session, and reproved for disregarding its authority, their protest against its claim to authority was maintained even there; and in the far greater number of instances, its interdicts were broken without any attempt being made to call those who did so to account. It is impossible here to enter into the details of this struggle, which was brought to a final issue by the judgment of the House of Lords in August 1842, affirming a decree of the Court of Session, which required the presbytery of Auchterarder to take the ordinary steps towards the settlement of the presentee to Auchterarder, without regard to the dissent of the parishioners. The law of the land being thus decided by the supreme court to be such as they could not with good conscience comply with, and parliament having rejected an application, in the form of a 'Claim of Right,' for an act such as would have reconciled the duties of their position according to the law of the land, in the church by law established, with what they believed to be their duty towards Christ and according to his law; it now seemed to the greater number of the ministers and elders holding the principle of the independence of the church, that the only course open to them was to retire from their position by the sacrifice of the emoluments and benefits of an establishment. And this they did at the meeting of the General Assembly on 18th May 1843.

Headed by Dr. Chalmers, Dr. Welsh, and others of the most eminent in the church, they left the appointed place of meeting of the General Assembly, St. Andrew's Church, Edinburgh, and proceeded to another place, previously prepared, Tanfield Hall, Canonmills, where, in the midst of a great concourse of people, the first General Assembly of the F. C. of S. was immediately constituted, and Dr. Chalmers was unanimously called to the chair as its moderator. Four hundred and seventy-four ministers renounced their connection with the Establishment, and along with them a great body of its elders and members.

Immediate steps were taken for completing the organization of the F. C., and extending it as much as possible into every district of Scotland. The forethought of Dr. Chalmers had already devised the SUSTENTATION FUND (q. v.). The F. C. undertook from the first the continued support of all the missions previously carried on by the Church of Scotland; and all the missionaries hastened to declare their adherence to the Free Church. An 'education scheme' was soon afterwards undertaken; and colleges for the training of ministers were founded in Edinburgh, Glasgow, and Aberdeen. Considerable opposition was at first experienced on the part of landowners, who refused to grant sites for churches and other buildings; but this gradually gave way. The bitterness of feeling which at first existed between the Established Church of Scotland and the F. C. has long since very much passed away.

The number of ministerial charges in the F. C. of S. is slightly above 1000. There are also numerous 'preaching stations,' in which preaching is regularly maintained, and other ordinances are administered under the care of presbyteries. Some of these are continually being added to the list of ministerial charges. The whole sum raised for religious and educational purposes by the F. C. of S. up to March 1873, or in about thirty years, was about £10,299,306, or rather more than £343,310 a year. In this are included the sums devoted to the erection of churches, mansees, school-buildings, colleges, &c. The Sustentation Fund now allows an 'equal dividend' of £160 to the ministers, with an addition of £30 or £15 in certain cases. The total sum raised in 1880-81 was £590,333.

Since 1843, the history of the F. C. has been generally that of peaceful progress. It has been agitated by questions respecting the administration of the Sustentation Fund, colleges, &c., which are of little interest to those beyond its own pale. It was brought into a litigation in the Court of Session, seeming to affect its fundamental principles. The minister of the F. C. at Cardross, in Dumbartonshire, having been suspended by the General Assembly of 1858, had recourse to the Court of Session, on the alleged ground of irregularity in the proceedings of the ecclesiastical judicatories, demanding the suspension of the sentence; and being on this account summarily deposed by the General Assembly, he raised an action in the Court of Session, not only claiming damages, but to have the sentence rescinded and found null and void. The case terminated in a recognition of the independence of the church in things purely spiritual, and a full admission

of its subjection to the civil courts in all things temporal, including the right of these courts to demand full information as to all ecclesiastical proceedings, and production of minutes and other documents, when they should see cause.

Negotiations towards union with the United Presbyterian Church gave rise to great dissension in the F. C. itself, from the unwillingness of many of its members to modify their profession of the doctrine of the lawfulness of the establishment of the church by the state; and it seemed as if a disruption of the F. C. was impending; but in 1873 the proposal of immediate union was laid aside, and peace in the F. C. restored. A similar proposal with regard to the Reformed Presbyterian Church was more successful, and the union was consummated in 1876.

FREE CITIES, the name given to those German towns, Hamburg, Bremen, Lübeck, and Frankfurt-on-the-Main, which were of themselves sovereign states and members of the German confederation. They are remnants of the once numerous 'Imperial' cities, or cities not subject to any superior lord, but immediately under the empire. Of the four F. C., Hamburg, Lübeck, and Bremen still retain their privileges under the re-constituted German empire; but Frankfurt (q. v.) was annexed to Prussia in 1866.

FREEDOM OF THE PRESS. See **PRESS**.

FREEHOLD, ESTATE OF (*liberum tenementum*, frank tenement). Real estates in England in the present day are divided into freehold and copyhold. By freehold property is meant all estates which owe no duty or service to any lord but the king. What are now known as estates of freehold were, under the feudal system, denominated frank tenements. They were held by the honorable tenure of Knight's Service (q. v.) and Free Socage (q. v.), and might have been held either of the crown or of a subject. But the statute of *Quia emptores* having abolished subinfeudation, all freehold estates, except those which have been held of subjects since the time of Edward I., are now held of the crown. A freehold estate must be an estate in fee, in tail, or for life; all other estates in land, as estates for years, are called chattel interests. An estate of freehold could in general be created only by livery of seisin of Feoffment (q. v.). By the doctrine of the feudal law, no person who had an estate of less duration than for his own life or for the life of another man, was considered to be a freeholder; and none but a freeholder was considered to have possession of the land. A tenant for years, &c., was regarded as holding possession for the freeholder. The possession of the freeholder might, however, be defeated by the wrongful act of the tenant; for a transfer of possession or livery of seisin by the tenant would divest the freeholder, and leave him to his Right of Entry (q. v.). This effect of a feoffment by wrong was abolished by 8 and 9 Vict. c. 106, s. 4. Before the time of Henry VI., all freeholders were entitled to vote on the election of a knight of the shire, as they still may for the appointment of coroner. But by 8 Hen. VI. c. 7, the famous statute was passed which still in great measure regulates the county elections, and enacts that no freeholder shall vote whose freehold is not of the value of at least 40s. a year. By 2 Will. IV. c. 45, s. 18, this qualification is continued as to all freeholds of inheritance, and to freeholders for life in actual occupation, or who have acquired their lands by marriage, marriage settlement, devise, or promotion to any benefice or office.

FREEHOLD LAND SCHEME had for its object to enable mechanics artisans, and other persons belonging to the lower classes, to purchase a piece of freehold land, of such yearly value as to entitle the owner to the elective franchise. Irrespective of any political object, benefit building societies now exist in most of the greater towns of this country, and are believed to be of great service to the laboring-man. See **BENEFIT SOCIETIES**.

FREE-LANCES were roving companies of knights and men-at-arms, who, after the Crusades had ceased to give them employment, wandered from state to state, selling their services to any lord who was willing to purchase their aid in the perpetual feuds of the middle ages. They played their most prominent part in Italy, where they were known as *Condottieri* (q. v.).

FREEMAN AND FREEDMAN. In the most general acceptance of these terms, the first implies one who has inherited the full privileges and immunities of citizenship; the second, one who has been delivered from the restraints of bondage, but who, usually, is not placed in a position of full social or even political equality with him who was born free. Though the words are Teutonic (being composed *frei*, free; and *mann*, a man or human being), the distinction between them depends on the constitution of Roman society. The equivalent for freeman (*liber homo*), indeed, comprehended all classes of those who were not slaves; but the distinction here pointed out was preserved by the application of the term *ingenuus* to him who was born free (Gaius, i. 11), and of *libertinus* to him who, being born in servitude, was emancipated. For the further development of this subject, as regards

the classical nations of antiquity, see **SLAVERY, CITIZEN**. As the organization of Roman society survived the convulsions of the middle ages to a far greater extent in the towns (see **MUNICIPALITY, MUNICIPAL CORPORATION**) than in the landward districts, where the institutions of feudality almost entirely superseded it, it is in the borough and other municipal corporations of this country, and of continental Europe, that we still find *freemen*, or persons inherited or acquiring by adoption, purchase, or apprenticeship, the rights of citizenship. See **FREEMAN'S ROLL**. But the idea of a freeman was by no means peculiar to the Roman or Romanized population of Europe; on the contrary, it belonged to the constitution of society in all the Indo-Germanic nations. Amongst those branches of them commonly known as Teutonic, it was generally based on the possession of some portion of the soil. In Anglo-Saxon England, the freemen were divided into *Ceorls* (q. v.) and *Eorls* (q. v.), or *Thanes* (q. v.). See **CITIZEN**.

FREEMAN'S ROLL. By 5 and 6 Will. IV. c. 76, commonly called the Municipal Corporations' Act, which placed the corporate towns, or, as they are denominated, the boroughs enumerated in the schedules A and B—i. e., nearly all the boroughs in England and Wales except London—under one uniform constitution, a distinction is made (s. 2) between the Freeman's Roll and the Burgess Roll.

Every person who, if the act had not passed, would, as a burgess or freeman, have enjoyed, or might have acquired, the right of voting in the election of members of parliament, is to be entitled to enjoy or acquire such right as heretofore. And it is further enacted (s. 5), that the town-clerk of each borough shall make out a list, to be called the *Freeman's Roll*, of all persons admitted burgesses or freemen, for the purpose of such reserved rights as aforesaid, as distinguished from the burgesses newly created by the act, and entitled to the rights which it newly confers; these last are to be entered on another roll, to be called the *Burgess Roll*. See **BURGESS**.

FREEMASON, FREEMASONRY. See **MASONS, FREE**.

FREE PORT (Ital. *porto franco*), is a harbor where the ships of all nations may enter on paying a moderate toll, and load and unload. Free ports form *dépôts* where goods are stored at first without paying duty; these goods may then be either re-shipped for export on paying a mere transit-duty, or they may pay the usual full customs of the country, and be admitted for home consumption. Free ports thus facilitate transit trade, and form, as it were, a foreign district within a state. See **WAREHOUSING SYSTEM**.

FREE-SPIRIT, BRETHERN OF THE, a fanatical sect of the middle ages, which was very generally (though sometimes secretly) diffused over Italy, France, and Germany, between the 13th and 15th centuries. They took their name from the 'freedom of spirit' which they claimed, in virtue of the words of St. Paul (Romans, viii. 2, 14), maintaining that the true sons of God are exempt from subjection to the law. They appeared first in Alsace, in the early part of the 13th c., and attracted notice by their singular attire and their fanatical proceedings, traversing the country in troops, accompanied by women, with whom, under the name of sisters, they lived in the greatest familiarity. Their doctrine was a species of pantheistic mysticism, which they applied with fearless consistency to all the details of the moral obligations. They held, according to Mosheim, who has collected the original authorities, 'that all things emanate from God, and will revert back into Him; that rational souls are part of the Divine Being; that the whole universe is God; that a man, by turning his thoughts inward, is united inexplicably with the First Cause, and becomes one with Him; and that those who are so immersed in the vortex of the Deity attain to perfect freedom, and are divested not only of the lusts, but even of the instincts, of nature.' From these principles, they inferred that the free man, thus absorbed in God, is himself God, and a son of God, in the same sense in which Christ is called the Son of God; and that, as such, he is raised above all laws, human and divine; to such a degree that, according to some of them, 'the godlike man cannot sin, do what he may; either because the soul, being elevated and blended with the divine nature, is no longer affected by the actions of the body, or because the emotions of the soul, after such union, become in reality the acts and operations of God himself, and therefore, though apparently criminal, and contrary to the law, are really good and holy, because God is above all law.'

These blasphemous and immoral principles, incredible as they may appear, are extracted by Mosheim, partly from the books of the sect, partly from the decrees of Henry, Archbishop of Cologne, by whom they were condemned. Principles such as these drew down upon the sect the arm of the state, as well as the censures of the church. No sect of the time suffered so much from the inquisition in the 14th century. They were regarded as offenders of public order and morality, as well as against the faith of the church. See **INQUISITION**. After the first appearance of the

sect in Alsace (1212), where its leader was a certain fanatic called Ortlieb (after whom the members are sometimes called Ortliebians), it spread into Thurgau and the Upper and Lower Rhine. During the latter part of that century, one of the leaders, named 'Meister Eckart,' had so large a following at Cologne, that the archbishop made his teachings the subject of a lengthened edict. The sect spread also into Swabia, where its members were confounded with the Beghards. In France, they were popularly known by the name 'Turlupins,' a word of uncertain etymology. We meet them in Bohemia in the beginning of the 15th c., and there is considerable similarity between their principles and those of the Adamites, who figure in Hussite history. From this date they are heard of no more.—See Mosheim, Soames's ed. ii. 582; also Gieseler's *Church History*, iii. 467, iv. 226.

FREE STATE, ORANGE. See **ORANGE RIVER FREE STATE.**

FREE-STONE, any rock which admits of being *freely* cut and dressed by the builder. In Scotland, it is synonymous with sandstone. It has also been defined as any rock which works equally freely in every direction, having no tendency to split in one direction more than another. In this sense, limestone and even granite have been called freestones.

FREE-TOWN—a name of the same significance as the *Liberia* of American origin to the south of it—the capital of Sierra Leone, a British settlement on the west coast of Africa. It is situated on the left bank of the Sierra Leone river, about five miles from the sea, in lat. 8° 29' N., and long. 13° 9' W. Pop. about 16,000. The town is pleasantly situated, and its wide streets are prettily ornamented with rows of orange, lime, banana, or cocoa-nut trees. The temperature, as one may expect from the locality, is tolerably uniform, varying in opposite seasons between the averages of 77°-6 F. and 80°-9. Towards the interior, F. is enclosed by the mountain-chain from which the colony is designated, a position to which the proverbial insalubrity of the climate is partly owing. The population, exclusive of the authorities and the garrison, consists almost exclusively of liberated negroes.

FREE TRADE. This term, when used so late as thirty years ago, expressed a disputed proposition, and was the badge of a political party; it now expresses the most important and fundamental truth in political economy. From its simplicity, it affords, to those who expect to make political economy an exact science, the hope that they have obtained at least one axiom. But it has in reality been established as the result of a double experience—the one being the failure of all deviations from it, the other the practical success of the principle during the short period in which it has been permitted to regulate the commerce of this country.

Trade consists in buying and selling. There is free trade when there is no interference with the natural course of buying and selling, if such interference be intended to improve or otherwise to influence trade. It is necessary to keep this distinction in view, because there are many laws not contrary to the spirit of free trade which interfere with buying and selling; for instance, in this country, it is unlawful to deal in slaves, because we do not acknowledge the right of one human being to be the owner of another; it is unlawful to sell intoxicating spirits without having obtained a license, because the tax for the license brings revenue to the Exchequer, and intoxicating liquors are a commodity which it is advisable to tax, in preference to the common necessities of life, or even harmless luxuries. There are many of these last which cannot be sold into this country without paying customs duty, but this is for the purpose of revenue merely, not as a restraint on trade.

The many attempts made by government to regulate trade for the purpose of benefiting the communities over which they ruled, may be divided into two great classes: the one prohibited the exportation of commodities, the other encouraged exportation, and prohibited or discouraged importation. The former was the old rule in this and in other countries. It was supposed that the wealth of the country depended on its retaining within itself certain productions of native growth or industry, and their removal out of the country was prohibited or restrained. Until a late period, the exportation of machinery was prohibited; but this was an exceptional remnant of the old principle, which had yielded to its converse, in which it was maintained that exportation is the source of wealth, and importation is a wasting of a nation's substance. On this theory the great body of British commercial and financial legislation, which received its death-blow in 1846, was founded. By it, a commercial community was then likened to an isolated human being possessed of a certain fund which he must of course spend, so as to become so much the poorer, if he buys commodities, which to him is equivalent to a nation's importing them. The notion was founded on the analogy of the miser, who will, of course, increase his store by restricting his purchases. Communities, however, are not in the position of the miser, possessing separate capital, which he can protect and increase; they rather resemble the merchant who buys and sells, making a profit

on what passes through his hands. Whatever communities import, they pay for by exports. This can be shown by analysis in any class of national transactions. If we pay for the goods we import by bills of exchange, these bills represent goods exported, otherwise they would not be paid. See **EXCHANGE**. If we pay for goods in bullion, it is the same thing; gold does not grow in this country, and every sovereign we send abroad to pay for goods has been got as the price of goods exported, unless it have been brought by any of our own people from the gold districts, and then it is virtually a produce of British industry. It is, in fact, a sort of dynamic law that importation causes exportation, just as a vacuum in physics is filled up by air, or the other nearest fluid.

As applied to the individual inhabitants, and not to the nation, free trade is the right of every man to do as he pleases with his capital and abilities; and as the general desire of mankind is to improve their condition, and, in fact, the greater portion of them are thoroughly devoted to this pursuit, the interests of the nation at large cannot be in better hands than in those of men who, by increasing their own wealth, are increasing the wealth of the public. The progress made by this country since 1846 has afforded a wonderful experimental illustration of this truth, since the exports have been tripled. They were, in round numbers, 40, and are now 250 millions. For more particular facts and circumstances connected with the establishment of free trade, see **ANTI-CORN LAW LEAGUE**, **CORN LAWS**, **CUSTOMS**.

FREE-WILL. The freedom or liberty of the will is the designation of a doctrine maintained in opposition to another doctrine, expressed by the term 'necessity.' The contest between these two views has been maintained in the fields both of theology and metaphysics. The idea of a man being 'free' in his actions appears first in the writings of the ancient Stoics. Afterwards in Philo Judæus, an Alexandrian Platonist, who flourished at the commencement of the Christian era, there occurs an inquiry propounded, 'whether it be not the case that the upright man is free, and the vicious man a slave.' This language was evidently meant to pay a compliment to virtue, and to affix a degrading stigma on vice, and ought not to have been too literally interpreted; for in strictness it might have been maintained with even greater plausibility, that the vicious man, who defies all restraints of society, has the greater liberty of the two. The doctrine of freedom, as applied to the human will, was first contended for by Pelagius against Augustine's doctrines regarding the operation of grace; and in a later age was the subject of controversy between Arminians and Calvinists, the Calvinists (such as Jonathan Edwards) having usually been Necessitarians.

Although in this dispute there are certain points of real difference of opinion between the opposing parties, yet the problem has been unnecessarily encumbered with the unsuitable phraseology that has accidentally invested it. The notion of 'freedom' is intelligible when we speak of a free man as opposed to a Russian serf, or of a free press as opposed to censorship; but with reference to human actions generally, it has no particular relevancy. When a man, urged by hunger, eats the food that is before him, we recognize two separate facts, the one leading to the other: the first is a painful feeling or sensation, the other a series of movements by which food is conveyed to the system; the one fact we call the motive, the other the action, of the will following on the motive; but there is no propriety in describing this sequence as either free or not free.

We may inquire into the greater or less certainty of the sequence—namely, whether a hungry man does always, as a matter of course, avail himself of the food presented to him, or whether one may be very hungry with the option of eating, and with no other motive operating to deter from the act, and yet not eat, thus showing an absence of uniform connection between pain and the movements for alleviating it; this would be a *real* question, and would throw light on the actual constitution of the human will; the question of liberty and necessity does not present us so much with an intelligible question as with an artificial difficulty made by inapplicable phraseology. It would have been much the same to have disputed whether or not the will is rich, or noble, or royal, merely because the virtuous and right-minded man has sometimes been commended by those epithets being applied to him. The word 'necessity,' also, is ill chosen, in consequence of its great ambiguity; being applied sometimes to logical and mathematical implication, as when we say the whole is greater than its part; sometimes to the rigorous uniformity of physical laws, such as gravitation; and at other times to what is merely a high probability, as when we expect that a man of honorable and upright character will speak the truth on some given occasion. See **NECESSITY**.

If we cast aside these confusing phrases, and inquire what is the real matter of dispute, we shall find that there are intelligible differences of opinion in reference to the sequence of human volition. It may be maintained that our actions have the same uniformity as the successions of the physical world; and this view

would be supported by a very wide induction of experience. It will be found that the whole of the complicated operations of society depend upon the certainty that men, in the same circumstances and under the same motives, will act in the same way. We allow for differences of individual character; but when once we have seen what any man is disposed to do in one instance, we take for granted that he will be similarly actuated when the identical circumstances are repeated. The whole of our trading operations are founded on the maxim that human beings prefer a greater to a smaller gain; and it has never been found that any portion of our race has taken a wayward fit, and contradicted itself on this point. We are prepared for exceptions to the rule, when other strong motives are present, but these are merely the intervention of a new force, not the suspension of the law that connects the other motive with its usual consequent. Nor is there anything degrading to human nature in this uniformity; while the opposite state of things would undermine all the securities of human life, and land us in a moral chaos. If human beings, who habitually dread pains and penalties, were suddenly, for no ulterior reason, to court hunger and cold, imprisonment and disgrace, it is obvious that there would be a speedy termination of man's career on the globe.

Still, the position thus contended for may be, and has been, called in question; or, at least certain exceptions to its universality may be put forward. We are able to comprehend the meaning of this counter-doctrine, even although we may find a difficulty in acceding to it. For example, Socrates drew a distinction between *human* and *divine* knowledge, intending by the one the departments of nature where strict law prevailed, and where by assiduous observation men might attain to certainty; such was the knowledge of the operative respecting his special craft, in which it was absurd to seek for any other source of insight than his own and other men's experience. But this did not include all knowledge. There was a department, the divine, reserved by the gods for their own special administration, and where they did not bind themselves to observe uniformity of dealing. This region included, according to Socrates, such great operations of the physical world as the motions of the heavenly bodies, the phenomena of weather and season. To be enlightened on these, it was necessary to consult the gods by oracle and sacrifice. Now, applying this view to the case of the human will, it might be maintained that, in the greater number of instances, and in all matters of primary importance, such as self-preservation, the uniformity of human actions must be admitted; but still there may be some deep, subtle, and refined operations, where the same motives sometimes lead one way, sometimes another, the whole situation being in every other respect identical. But it lies with the supporters of this view to substantiate their exceptional cases in the midst of so much evident uniformity. As yet, nothing of the kind has ever been proved, and our only safe ground, philosophically, is what is our safe ground practically—namely, to abide by the doctrine of law in *all* human actions, on which we have not the smallest scruple as respects the preponderating mass of them.

The partisans of liberty, who take up the ground of opposition to uniform law as now expounded, not infrequently express themselves to the following effect. Granting that the emotions of the mind have a uniform efficacy as motives, and that he that has a musical taste will be found on all occasions acting in conformity with it, still the emotions are not the whole of the mind. We have, in our mental composition, Feelings, and Intelligence, and Activity; but these do not make up our entire being. There is a something that all these inhere in, a substratum or support, which we call our 'self,' the 'ego,' or 'I,' and this abstract self is exempt from the conditions that attach to these attributes of self. This ultimate personality of every human being is free and independent, being exempt from the laws whereby our several feelings operate as motives to our ordinary actions. A self-determining power is supposed to reside here, even if excluded from the other mental adjuncts. It is considered unphilosophical and incorrect to resolve the whole of mind into feelings, actions and intellect; these are mere attributes of an inexplicable something which each one is conscious of, and recognizes as the essence or center of the mental being, while they are merely properties or attributes. Granting the existence of this inner self, there is said to be sufficient scope for a properly free agency, without going the length of supposing that men are to contradict themselves in the everyday conduct of life.

Such a mode of stating the doctrine of liberty, however, is liable to the charge of logical confusion, not to speak of the difficulty of establishing the existence of the entity in question. If we were to inquire into what constitutes the *essence* of mind, the thing which being present constitutes mind, and whose absence is the negation of mind, we might perhaps not be able to come to a conclusion that all philosophers would acquiesce in. It is always reckoned a very abstract and metaphysical discussion to settle the essence of things; even as regards *matter*, this is not an easy question. But if 'essence' is to mean something, and not

absolutely nothing, it must point to some power, property, or quality, capable of being named and signalized. Thus, we might say the essence of material bodies is the quality variously named, as resistance, momentum, inertia; all which imply that one body is at once an obstruction to other moving bodies, and a moving power when once in motion; but if any one insists that this is but one of the attributes of matter, in common with weight, extension, color, &c., and that there must be something still deeper, in which all the various qualities inhere, we can only answer that we know of no such essence or substratum, and are incapable of conceiving any such. We may fix upon the most fundamental, the most universal, and ineradicable quality of a thing, such as this property of resistance as regards material bodies, and term that the essence; while any other attempt at discovering an essence would only end in setting up fictions. So in the case of mind. If we are called on to specify any one aspect of our mental constitution more universal and fundamental than the rest, with a view to setting forth the essence of mind, we should be obliged to select *volition*, or action governed by feeling, as the main or central fact. Wherever we can prove the existence of feeling, and of an activity controlled by that—as when an animal uses its organs to preserve its own life, to cater for pleasures, and ward off pains—we should have to admit the reality of mind, although, perhaps, the intelligence were of the lowest kind. Any being not possessing both sensibility and the power of acting in accordance with it, could not be said to possess a true mental nature. We should not trouble ourselves with considering the possible existence of a mystical 'ego,' but should at once declare that such a being did not come up to the standard or definition of mind. Will, or volition, as thus explained—namely, the direction of the active organs of a living creature to chime in with its various feelings—is itself the essence or substratum of mind, as resistance is the essence of matter. Wherefore, to speak of feelings and actions as something apart from 'ego,' but inhering in it, is merely to count the same fact twice over, or to call a thing the attribute of itself. Volition *is* mind, and not an attribute of mind; and when we have specified the power of voluntary, or feeling-guided action, and a certain amount of intelligence, varying greatly in individuals, we have specified everything that can belong to any individual man or animal; an 'ego' beyond this is something inexplicable and fictitious. It cannot, therefore, be admitted that any foundation is given to a supposed 'free agency,' by referring to this occult and imaginary essence, any more than it would be competent to claim exceptions to the great physical laws that govern material bodies, by assuming an occult essence of matter with powers and properties at variance with its inertia, weight, extension, and other known qualities.

In one respect, the mind is differently situated from the material world in all that regards the power of tracing strict uniformity, and predicting the future from the past. Each one of us has direct access to our own feelings, but only an indirect and imperfect access to the feelings of another person. Excepting self, we can never know the whole of what any one feels; our best observations and reasonings are but approximations to the truth, and predictions founded on them are liable to be falsified through unseen forces in the arcanæ of another man's individuality. Admitting the uniformity of sequence of motive and act, we are never able to exhaust the motives of any single mind, beyond our own; and thus each one may be said to move in a certain inner circle of the impenetrable and unpredictable, while the large mass of the everyday actions of all human beings follows an almost undeviating regularity. This is a very important distinction between mind and matter, although not invalidating the great general fact of uniform law, as attaching to the one no less than to the other. For a sketch of the history of this great controversy, see Dugald Stewart's *Active Powers*.

FREEZING AND FUSING POINTS. See FUSING POINTS.

FREEZING MIXTURES, AND OTHER MEANS OF COOLING.

When matter passes from the solid into the liquid state, heat in large quantity disappears, and ceases to affect the thermometer. See *HEAT*. The chemist avails himself of the fact that heat disappears during liquefaction, for the purpose of procuring artificial cold. When a piece of ice having a temperature of 32° F. is placed in its own weight of water at 174°, we find, on testing the water with the thermometer after the ice has melted, that its temperature is 32°; the heat which the water contained having disappeared during the melting of the ice. As water in passing from the solid to the fluid state possesses the property of rendering latent a greater amount of heat than any other substance, it is, when in a solid form, as ice or snow, or when combined with salts, as water of crystallization, a powerful agent in producing artificial cold.

The substance employed in freezing mixtures should be finely powdered, rapidly mixed, and placed in vessels with little conducting power. The following are a few of the important formulæ for these mixtures: 1. A mixture of two parts of

pounded ice or of fresh snow and 1 part of common salt, causes the thermometer to fall to -4° . 2. A mixture of 5 parts of commercial hydrochloric acid and 8 parts of powdered crystallized sulphate of soda, causes a reduction of temperature from 50° to 0° . 3. Equal parts of water, of powdered crystallized nitrate of ammonia, and of powdered crystallized carbonate of soda, produce a cold of -7° . 4. A mixture of 3 parts of crystallized chloride of calcium, previously cooled to 32° , and 2 parts of snow, produces a cold of -50° , which is sufficient to freeze mercury. 5. By dissolving solid carbonic acid, or solid nitrous oxide gas, in sulphuric ether, temperatures of from -120° to -146° may be obtained, at which alcohol passes to the consistency of oil, and finally to that of melted wax. This is the most powerful freezing mixture that is known.

The freezing mixtures used by confectioners and those that are most convenient for ordinary experimental purposes, are the first and second of the above list.

When matter passes from the liquid to the æiform state, heat also disappears, and the knowledge of this fact has been applied to the cooling of liquids, and to the actual production of ice. If a glass bottle containing water be covered with a cloth, which is kept constantly wet by the application of water, the evaporation from the wet cloth will soon diminish the temperature of the contents of the bottle, and if the cloth were moistened with alcohol or with ether, the cold would be proportionally greater, the degree of cold varying with the rapidity and extent of the evaporation. Wine-coolers, or water-coolers, made of porous earthenware, act in the same manner as the cloth. They are soaked in, and saturated by water, which by its evaporation occasions cold. Coolers of this kind are common in most hot countries. On the ancient monuments of Egypt, a man is sometimes represented as fanning these vessels with a palm-leaf, to promote evaporation, and the Arabs in that country still practice this custom. See REFRIGERATING-MACHINES.

In some parts of India, where the dryness of the air allows a considerable evaporation to take place, ice is obtained in the following manner: 'Flat, shallow excavations, from one to two feet deep, are loosely lined with rice-straw, or some similar bad conductor of heat, and upon the surface of this layer are placed shallow pans of porous earthenware, filled with water to the depth of one or two inches. Radiation (see HEAT) rapidly reduces the temperature below the freezing-point, and ice is formed in thin crusts, which are removed as fast as they are produced, and stowed away in suitable ice-houses.'—Miller's *Elements of Chemistry*, 2d ed., vol. i. p. 220.

FREEZING-POINT. See THERMOMETER.

FREGENAL DE LA SIERRA, a town of Spain, in the province of Badajoz, and 300 miles south-east from Badajoz. It stands in a valley among mountains on the right bank of the Martiga. The streets are wide and well paved, and the houses in general well built. There is an ancient castle, erected by the Templars, within which is the bull-ring, capable of containing 4000 people. Leather and linen fabrics are extensively manufactured. Pop. (1877) 7707.

FREIBERG, an ancient city of Germany, the center of administration for the Saxon mines, is situated on the northern slope of the Erzgebirge mountains on the left bank of the Münsbach, not far from its confluence with the Mulde, 20 miles south-west of Dresden. It owes its origin to its silver-mines, discovered about the year 1190. It is still surrounded by old walls and towers, and contains many interesting buildings and institutions, of which the principal are the town-house, dating from 1410, and the cathedral (1484—1512), two stately Gothic edifices, and the Berg-Academie, or School of Mines, founded in 1765, the most famous institution of the kind in Europe. At the Berg-Academie, instruction is given by professors in surveying, mining, the preparation of ores, geology, mineralogy, &c. It possesses lecture-rooms, a library, and mineralogical and geological collections; and has attached to it three separate laboratories, and an office for the sale of minerals. Humboldt, Werner, Jameson of Edinburgh, and many other eminent geologists and mineralogists, studied at this institution. There are, it is said about 150 mines of silver, copper, lead, and cobalt around Freiberg. The manufactures consist principally of articles in imitation of gold and silver ware, of white-lead, gunpowder, iron and copper wares, &c. In the 17th c., it was a place of great wealth, and had a pop. of 40,000. The mines, however, have of late greatly fallen off, owing either to the richest veins being exhausted, or to the shafts being driven so deep that the water cannot be drained off from them. Pop. (1880) 25,445.

FREIBURG, or **FRIBOURG**, a canton of Switzerland, bounded on the N. and E. by Bern, and on the S. and W. by Vaud and the Lake of Neuchâtel. It has a superficies of 642 square miles, and according to the census of 1880, a population amounting to 115,400, of whom near 100,000 were Catholics. More than two-thirds of the inhabitants are French; the remainder are Germans. The official language is French, but all the laws and decrees

binding on the whole canton are published both in French and German. The surface of the country is hilly, the mountains in the south of the canton forming a continuation of the Bernese Alps, and rising in the highest points upwards of 7000 feet high. The principal rivers are the Saane or Sarine—which traverses almost the whole extent of the canton from its southern to its northern extremity—and the Broye. The country abounds in excellent meadows and rich pastures, upon which are reared the strongest horses and the best breed of cattle in the whole of Switzerland; indeed, the great part of the wealth of the canton consists in cows, sheep, goats, and horses, of which in proportion to its area there are great numbers. Dairy husbandry, and especially cheese-making, is pursued with great success; 40,000 cwt. of cheese are said to be made yearly. There are considerable manufactures of straw-plat, leather, cherry brandy, and tobacco. F. was received as a member of the Swiss confederation in 1481, and in 1848 a liberal constitution was established. It sends six members to the national council.

FREIBURG, or **FRIBOURG**, a town of Switzerland, capital of the canton of the same name, is situated on both banks of the Sarine, but chiefly on a hilly promontory formed by one of its windings, about 18 miles south-west of Bern. Seen from some distance, the town has a highly imposing and picturesque appearance. Houses climb to the top, and extend to the very edge of the precipice that overhangs the river, and in another portion of the town they form terraces, the roofs of one tier being on a level with the pavement of another; while the whole is surrounded by a long rising and falling line of embattled walls, with watch-towers and gateways of ancient fortifications which still exist in a perfect state. The banks of the Sarine are united by four bridges, one of them a suspension-bridge, 906 feet long, 23 feet wide, and 175 feet above the stream, the longest bridge of a single span in the world—about 300 feet longer than the Menai Bridge. Another suspension-bridge spans the gorge of Gotteron, and is about 700 feet long, and 317 feet above the valley beneath. The church of St. Nicholas, a fine Gothic structure, has an organ built by a native of F., which has 7800 pipes, one of them 32 feet long, and is considered the finest toned instrument in Europe. This church has also the highest spire and finest set of bells in Switzerland. The other principal buildings are the Cantonal School (previous to 1848 the Jesuits' College), the most conspicuous building of the town; and the Lyceum. The inhabitants of the upper portion of the town speak French; in the lower portion, German is spoken. F. has few manufactures; the chief are woollens, hardware, leather, pottery, and tobacco. Pop. (1880) 11,546, of which only 500 are Protestants.

FREIBURG, a town of Germany, in the grand duchy of Baden, capital of the circle of the Upper Rhine, is the seat of an archbishop, and is situated on the Dreisam, on the western border of the Black Forest, 42 miles south-south-east from Strasburg. It is an open, well-built town; the walls and ditches with which it was formerly surrounded, have been converted into promenades and vineyards. The Minster or Cathedral of F. is one of the most beautiful and perfect specimens of Gothic architecture in Germany. It is cruciform, and built of red sandstone, was begun in 1122, and not thoroughly completed till 1513. It has a tower 367 feet high, remarkable for its elegance and lightness. In one of its chapels, the University Chapel, there are, among other pictures, a Nativity and an Adoration by Holbein, the latter considered one of his most successful pictures. The university of F. was founded in 1456; in 1875 it had 48 professors and teachers, and 318 students. The Exchange (*Kaufhaus*) is a quaint Gothic structure of the 16th century. The chief manufactures are chicory, tobacco, paper, potash, &c. Pop. (1880) 36,382, of whom about 2500 are Protestants.

FREIGHT (a word having the same origin as 'fare'), the hire of a ship, or part of a ship, for the transport of merchandise; also the merchandise so transported. The agreement for the service is termed a Charter-party (q. v.).

If a merchant freight a whole ship, but neglect to fill it, the captain is not at liberty to complete the cargo from other sources, without accounting to the merchant for any moneys received for such additional load. On the other hand, if the merchant covenant to freight a certain portion of a ship, he is bound to pay the sum agreed on for that portion, notwithstanding that his goods may fail to occupy as much space. If, in the charter-party, a day be appointed for sailing, and either the merchant fail to have his goods ready for embarkation by the time fixed, or the vessel be unprepared to start—wind and weather permitting—the agreement may be declared void by the aggrieved party, who can also recover at law for any detriment caused to his property in consequence of the delay. The use of charter-parties has been traced back as far as the reign of Henry III.

This contract, which in England, and generally in the commercial language of this country, is called freight, is more commonly spoken of by the legal writers of Scotland as Affright-

ment, from the French *affrètement* (Bell's *Com.* i. p. 414), but there is no essential difference in the laws of the two countries with regard to it. Throughout the whole commercial world, indeed, in so far as its provisions are not made the subjects of positive stipulation either by Charter-party or Bill of Lading (q. v.), they will be held to be in accordance with the usage of trade, and of that particular branch of trade to which the hiring has reference.

It was formerly held that the payment of the wages of the crew was contingent on the earning of freight by the ship, in accordance with the maxim of Lord Stowell, that 'freight is the mother of wages.' But this rule, which was already subject to many exceptions, has been abrogated by the Merchant Shipping Act (17 and 18 Vict. c. 104), and wages may now be recovered either by seamen or apprentices, even though no freight has been earned by the vessel. The seaman has a right to cling to the last plank in satisfaction of his wages; but in cases of shipwreck, his claim for wages will be barred if it be proved that he did not exert himself to the utmost to save the ship, cargo, and stores. This provision was first introduced by 7 and 8 Vict. c. 112, s. 17, which enacted that, in order to enable him to recover his wages, the seaman should be bound to produce a certificate from the master, or chief surviving officer of the ship, to the effect that he had so exerted himself. By s. 183 of 17 and 18 Vict. c. 104, the onus of proof is very properly laid on those who impugn the conduct of the seaman. The old rule is still adhered to in America, but it is not applied to the master, and it does not hold with reference to seamen, if the freight has been lost by the fault either of the master or owner; e. g., if the ship has been seized for debt, or for having contraband goods on board. See Kent's *Com.* iii. pp. 266, 267.

FREILIGRATH, FERDINAND, a brilliant lyric poet of Germany, was born at Detmold, in the principality of Lippe, 17th June 1810. He attended the high school in his native town till the year 1825, when he entered a merchant's office, first at Soest, and afterwards at Amsterdam. Encouraged by the favorable reception of his poems, he abandoned mercantile pursuits, married, and removed to Darmstadt.

In 1842, a pension was bestowed upon him by the king of Prussia, whereupon he removed to St. Goar, on the Rhine. This circumstance, and his poem *Aus Spanien*, deprived him of the sympathy of the liberal party, which, however, was restored to him twofold when, in 1844, he gave up his pension, and in his political poem attached himself to the democratic party. The publication of his *Glaubensbekenntnisse* (Confession of Faith), in the same year, compelled him to take refuge abroad. He went to Belgium, Switzerland, and in 1845, to London, where he resumed his mercantile pursuits, and became correspondent for the banking-house of Huth & Co. He was about to accept an invitation to America, sent him by Longfellow, when the events of 1848 recalled him to his native country. F. settled in Düsseldorf, where he became the most important member of the democratic party, and sang the praises of democratic socialism. He was impeached on account of his poem *Die Todten an die Lebenden* (The Dead to the Living). The interest felt in this trial was extraordinary. F. was defended by celebrated advocates, who did not fail to ridicule the folly shown in prosecuting a man for writing poetry. The doctrine that the poet is a 'chartered libertine' in the expression of his sentiments, carried the day, and F. was acquitted, 3d October 1848. The consequence was inevitable. His poem immediately became the rage; the first edition was sold off in Düsseldorf within a few hours. A second prosecution induced F. again to withdraw from his native country, and from 1849 to 1868 he resided in London. In the latter year, he returned to Germany, and made Stuttgart his home. Several songs, written by him there at the beginning of the Franco-German war, have attained great popularity. F.'s principal productions are his *Gedichte* (1838; 27th edit. 1871); *Ca Ira!* (1846); *Die Revolution* (1848); and *Neuere politische und sociale Gedichte* (1849). Complete editions of his works appeared at New York (6 vols. 1858—1859), and at Stuttgart (6 vols. 1870; 2d ed. 1871). F.'s poems display lively imagination, fire and melody of rhythm, a richness of execution, and a picturesque originality of style which not seldom, however, passes into eccentricity and merely 'spasmodic' force of expression. His translations from English poets are admirable. F. died at Cannstadt, near Stuttgart, on March 18, 1876.

FREIRIRA, a seaport of Chili, in the province of Atacama, at the mouth of the Guasco. It is a place of some trade. Pop. 10,000.

FREISCHÜTZ, the freeshooter, is the name given in the legend to a hunter or marksman who, by entering into a compact with the devil, procures balls, six of which infallibly hit, however great the distance, while the seventh, or, according to some versions, one of the seven, belongs to the devil, who directs it at his pleasure. Legends of this nature were rife among the troopers of Germany of the 14th and 15th centuries, and during the Thirty

Years' War. The story first appeared in a poetic form in 1810 in Apel's *Gespenssterbuch* (Ghost-book, 1810—1815), and F. Kind adapted the story (1843) to the opera composed by Weber in 1821, which has made it known in all civilized countries.

FREISING, a town of Bavaria, is situated in a fruitful, agreeable district on the left bank of the Isar, 20 miles north-east of Munich. The town was the seat of an episcopal prince till 1802, when the see was secularized. The bishopric of F. dated as far back as 724 A.D., but its bishops were first made princes by the Emperor Ferdinand (1619—1637). The chief buildings are the palace formerly of the bishop, and a beautiful cathedral, dating from the 12th c., having three naves, two towers, and a singular crypt, the pillars of which have monsters crawling up their shafts. Pop. (1880) 8850, who carry on brewing and distilling, and manufacture vinegar, tobacco, saltpetre, &c.

FRÉJUS (anc. *Forum Julii*), a small town of France, in the department of Var, is situated a mile inland from the embouchure of the Argens (anc. *Argentæus*) into the Mediterranean Sea, and 15 miles south-east of Draguignan. It was originally a colony from Marseille, and was afterwards colonized anew by Julius Cæsar, and called Forum Julii. It has remains of ancient Roman walls, and of a Roman circus and viaduct. The ancient harbor, at one time the most important Gallic port, and in which Augustus posted the fleet of 300 galleys which had been captured from Antony at Actium, has become silted up. Here, or rather at the new harbor of St. Raphael, 1½ miles off, Napoleon landed on his return from Egypt in 1799, and embarked for Elba in 1814. Pop. (1876) 2791.

FREMONT, JOHN CHARLES, an eminent American traveler and explorer, son of a French emigrant gentleman and a Virginian lady, was born at Savannah, Georgia, January 21, 1813. He lost his father at the age of four years, and removed to Charleston with his mother, where, at the age of 15, he entered Charleston College. For two years he taught mathematics on board the sloop-of-war *Natchez*, received his degree in 1835, and soon after passed a rigorous examination for the post of professor of mathematics in the navy, and was appointed to the frigate *Independence*; but resolving to quit the sea, he turned his attention to civil-engineering, and was employed in the Mississippi survey, and similar undertakings. In 1840, he received from President Van Buren a commission as second-lieutenant in the corps of Topographical Engineers, and was ordered to make an examination of the river Des Moines, upon the western frontier. In 1841, he married the daughter of Colonel Benton. He now proposed to penetrate the Rocky Mountains, and, his plans being approved of, he reached and explored the South Pass in 1842, with only a handful of men. He thus demonstrated the feasibility of an overland communication between the two sides of the continent, and discovered the route to California, since followed by thousands. During the whole of his journey, he made careful barometrical and astronomical observations, and noted attentively the geography, botany, and geology of the district. A lofty peak which he ascended, 13,750 feet above the sea, is now called Fremont's Peak. His report of the expedition was laid before Congress in the winter of 1842—1843, and attracted great attention both at home and abroad.

He immediately planned a second expedition more extensive than the first, and determined to survey the then unknown regions lying between the Rocky Mountains and the Pacific Ocean. He commenced his journey in May 1843, explored the Kansas River, crossed the South Pass, and, after 1700 miles of traveling, came, on September 6, in sight of the Great Salt Lake, of which very vague and erroneous notions were entertained. He advanced as far as Fort Vancouver, 90 miles from the mouth of the Columbia River, and then commenced his return. He selected a route leading to the Upper Colorado, through an almost unknown region, crossed by rugged mountain-ridges. He soon encountered deep snows, and found himself in a bare and desolate country, with the prospect before him of death from cold and hunger to his whole party. After suffering the greatest hardships, he determined to make for San Francisco instead of the United States, and when he could get no Indian to guide him across the snow-covered mountains which lay between him and the valleys of California, he boldly undertook the passage without a guide. He accomplished it in 40 days, reaching Sutter's Fort on the Sacramento, early in March, with his men almost reduced to skeletons, and only 35 out of 67 horses and mules remaining, and those so weak and thin that they could barely walk. He proceeded southward, along the Western range of the Sierra Nevada, crossed that range through a gap, entered the Great Basin, and reached Washington in August 1844. The remainder of the year was taken up in preparing his report. In consideration of his valuable services, F. was brevetted captain in January 1845, and in the spring of the same year set out on a third expedition to explore the Great Basin and the maritime region of California. He took part in the war with Mexico, and cleared the northern part of California from Mexican troops. He then became involved in a

dispute between two of his superior officers in regard to the right of command in California, which led to his trial by court-martial, and the unjust deprivation of his commission. The president offered to reinstate him, but as it was justice and not favor that he demanded, he resigned his position in the army.

In 1848, he started upon a fourth expedition, at his own expense, trying to find a practicable passage to California along the upper waters of Rio Grande. In attempting to cross the great Sierra covered with snow, his guide lost his way, and P.'s party encountered horrible suffering, being even driven to cannibalism to support life, and losing one-third of their numbers. In 1849 he settled in California, and in the same year was elected senator for that state. In 1850, Baron Humboldt, on behalf of the king of Prussia, sent him 'the great golden medal for progress in the sciences,' while at the same time the Geographical Society of Berlin made him an honorary member. The Royal Geographical Society of London also awarded him the 'founder's medal for pre-eminent services in promoting the cause of geographical science.' In 1853 he conducted a fifth expedition along the route of the fourth. In 1856 he stood for the presidency. In 1861 he was made a major-general, but gave up his command in 1862. In 1864 he was again nominated for the presidency, but withdrew. In 1873 he was found guilty at Paris of fraud in connection with his scheme for a southern railway to the Pacific.

FRENCH BEANS. See KIDNEY BEANS.

FRENCH BERRIES, Avignon Berries, Persian Berries, or Yellow Berries (Fr. *Graines d'Avignon*), small berries, the fruit of certain species of Buckthorn (q. v.), but principally of the Yellow-berried Buckthorn (*Rhamnus infectiorius*) used by dyers in dyeing yellow. For this purpose, they are gathered unripe, and dried; they yield a rich yellow color, but it is fugitive, and on this account the use of this dye-stuff has very much given place to that of mineral dyes. It is, however, still imported into Britain from the Levant and from the south of France. That from the Levant is the best. The yellow-berried buckthorn is a very spreading procumbent shrub, with ovato-lanceolate smooth leaves, growing naturally in rough rocky places in the countries near the Mediterranean. It is cultivated to some extent in the south of France.

FRENCH HONEYSUCKLE (*Hedysarum coronarium*) a beautiful biennial plant of the natural order Leguminosæ, sub-order Papilionaceæ with branching and spreading stems, pinnate leaves, scarlet or sometimes white flowers, and jointed pods, which have one seed in each articulation. It has fine foliage, and a very elegant appearance, and is often to be seen in flower gardens. It is a native of the south of Europe, and is there pretty extensively cultivated as food for cattle. It grows to a height of four or five feet, yields a large crop and is very nutritious. It is used either in a green state, or dried as hay. It requires a rather warmer climate than that of England for its profitable cultivation. The genus *Hedysarum* contains many species, extensively diffused over the warmer parts of the world. A few are found in cold regions as *H. fruticosum* in Siberia, growing in sandy soils, very useful in fixing them by its roots, and valuable as affording food for horses.

FRENCH LANGUAGE AND LITERATURE. The *French language* has been developed under the combined influence of numerous forms of speech, among which Latin, as in every other tongue of Western Europe, takes a principal part. It would appear that in the 4th and 5th centuries of our era, the whole of Gallia, from the Rhine to the Pyrenees, had adopted the language of the Roman conquerors, not the polished speech of the classic writers—the *sermo urbanus*—but the form of Latin that had become common to all the subjugated provinces of Central Europe—*lingua Romana rustica*. Suetonius, Pliny, Juvenal, and Martial make frequent reference to the Latin in use in Southern Gaul and Spain; and in the 4th c. we find that, under the Emperor Theodosius, the Roman Senate was addressed by an orator of Gaul in rude and uncultured transalpine Latin. At this period, and much later, Latin was employed in the provincial assemblies of Gaul; but in the 7th c., two other forms of speech had come into general use—a provincial dialect of the *lingua Romana*, and a form of German known as the *lingua Theotisca*. The latter which was probably a mingled jargon, used in common by the Frankish and Teutonic tribes, and consequently in vogue in the north and east, received a more definite development under Charlemagne, who caused a grammar of it to be prepared for the use of the schools which he had established, and in which it was taught conjointly with Latin.

The council of Tours (813) recommended the use both of the rustic Latin and the Teutonic dialect; and in 842, in the compact made between the two brothers, Charles the Bald and Louis the German, the former swore in the *Romana rustica*, and the latter in the *Teutsche* language, which, although it had been generally spoken at the court of Charlemagne, had already given place in France to the Frankish form of Latin. This Gallo-Romanic idiom

early branched off into the two characteristically different forms of the *Provençal* or *Langue d'oc* of the south, and the *Roman Wallon*, or *Langue d'oïl* of the north. The comparative prosperity which the south of France enjoyed, first under the kings of Arles, and subsequently under the counts of Provence, its freedom from foreign aggression for several centuries, the beauty of the climate, and the more thoroughly Romanized character of the people, led to the early development of the Provençal, and, by the lips of the troubadours, breathed forth a rich melody of song, which, after a time, was re-echoed in less harmonious tones by the *trouvères* of the north in their ruder tongue. The earlier productions of these two schools exhibit striking differences in diction, inflection, and construction; and while the troubadour sang of love, and dwelt on the beauties which a southern climate and a fruitful soil scattered broadcast over the face of nature around him, the northern *trouvère* invented a chivalrous mythology of his own, and ascribed to the heroes of Greece and Rome, and the brethren in arms of King Arthur and Charlemagne, the sentiments of his own times. The use of the northern or Walloon French was very considerably extended through its adoption by the Normans, who in time carried it under William the Conqueror to England, and, under the northern leaders of the Crusades, to the south and east. In the south, on the contrary, the cruel persecutions of the Albigenses, against which the troubadours inveighed aloud, checked the development of the Provençal language; for the songs of the troubadours were proscribed, and thus the use of the *langue d'oïl* soon extended with the spread of northern power into the provinces of Provence and Languedoc. One of the earliest monuments of the French-Walloon, in the form in which it shows evidence of its gradual development in modern French, is the *Roman de Rou*, a versified chronicle of the exploits of Rollo and his successors, composed by Robert Wace. In this composition, the language is no longer the sonorous, many-vowelled Provençal, or the mongrel Latin of the *lingua rustica*, but a distinct form of speech. The language thus formed by the ingrafting of Norman, Frankish, and Teutonic idioms on the degenerated Latin of the Gallic provinces, was rapidly developed under the fostering influence of the university of Paris and the Sorbonne, which already, in the 13th c., attracted the learned men of all nations to their schools. The *Roman de la Rose*, begun in the 13th c. by Jean de Meung, and completed in the 14th c. by G. de Lorris, and *Guyot's Bible*, belonging to the same period, are typical of the literature of France in the middle ages, which consisted chiefly of tales of chivalry, and coarse sallies against the clergy.

Fróissart's chronicles of the 14th c., which afford a vivid picture of the wars of the English and French, in which he himself took an active share, are written in a dialect that is quite comprehensible to the modern student. Comines, who wrote in the 15th c., is a less picturesque narrator; but he may be classed among the earliest true historians of his country, for he was one of the first who observed public events with judgment, and recorded what he had seen in a straightforward, truthful manner. Francis I., by his love of music, song, and dramatic representations, gave indirect encouragement to literature; while the French language acquired force and terseness through the writings of Rabelais, Ronsard, Amyot, and Montaigne; and although, under the regencies of Catharine and Marie de' Medici, Italian writers were more patronized at court than native authors, the language and the literary talent of the nation were undergoing a process of gradual development, which was completed by the establishment, under the auspices of Richelieu, of the *Académie Française* in 1634. At this period, Corneille brought French tragedy to its highest point of grandeur in the classic style of the drama, which he had adopted. His best pieces are *Le Cid*, *Les Horaces*, *Cinna*, &c. Pascal, in his *Lettres Provinciales*, established a standard of French prose; while Descartes, in his *Discours sur la Méthode*, showed the adaptability of the language to subjects requiring conciseness and precision. A long galaxy of great names gave splendor to the reign of Louis XIV. in every branch of literature. Notwithstanding the frivolity of the habits of the higher classes in France during this period, no age produced more vigorous writers or original thinkers. Bossuet and Flechier won respect by their noble funeral orations; Bourdaloue and Massillon, by their eloquent preaching; Fénelon, by his learning and earnest exhortations; and Pascal, by his Christian view of the great questions of human experiences. In dramatic literature, Racine and Molière stand forth conspicuous among a host of lesser writers, the former pre-eminent in tragedy, as his *Andromaque*, *Iphigénie*, *Phèdre*, testify; the latter inimitable in comedy, and exhibiting wonderful powers of delineating human character from a humorous point of view, that have never been surpassed. Among his best pieces we may instance *Tartuffe*, *Le Misanthrope*, and *Les Femmes Savantes*. La Fontaine is alike well-known among his countrymen for his moral Fables and his licentious Tales. La Rochefoucauld and La Bruyère, in their *Sentences* and *Caractères*, depicted human character, with its peculiarities, inclinations, and foibles in strong, humorous, and vivid touches. This was the age of Memoirs and

Letters: in the former branch of contemporary history, Cardinal Retz was perhaps the most successful of the host of writers who gained a reputation in this special department of literature; while Madame de Sévigné's letters are models of easy epistolary style, and afford a lively picture of the times. This age, in which, at anyrate, the *semblance* of religion had been respected, was followed by one of scepticism, infidelity, and philosophical speculations of the wildest kind. Four men of genius, Montesquieu, Voltaire, Rousseau, and Buffon, contributed, to a very great extent, by their writings, and the influence which they exerted on the minds of their contemporaries, in bringing about the Revolution.

Montesquieu, by his philosophical dissertations on the laws and government of his country, taught the French to take more enlightened views of the rights and duties of different classes of society, and thus naturally roused the angry passions of the oppressed lower orders; while the passionate eloquence of Rousseau won a hearing for doctrines which were entirely subversive of moral obligations, and recognized no higher standard than human inclinations. Voltaire's versatility of powers, which were exercised with equal ease, and nearly equal success, on tragedy, satire, romance, poetry, history, and philosophy, enabled him, to the end of his long life, to maintain the supremacy over public opinion, which he had won in his youth. Buffon devoted himself to the study and description of nature, and his *Histoire Naturelle*, which inaugurated a new era in the literature of natural history, is a remarkable monument of the science and learning of that period. Diderot, and D'Alembert the geometer, founded the *Encyclopédie*, which, while it gave a lucid summary of numerous branches of human knowledge, was always hostile to religion. The Revolution, which had been materially accelerated, if not produced, by the inspirations of men of consummate intellect, was not favorable to literature. A period of almost complete intellectual torpor succeeded the active mental development that had characterized the preceding classic and philosophic periods. The Empire was scarcely more propitious to learning; but with the *Corinne* and *L'Allemagne* of Madame de Staël, and *Les Martyrs* of Chateaubriand, a reaction took place; and these productions of the new romantic school were soon followed by numerous others, either belonging to the same, or to the rival classical school. Among the host of young and original writers who now acquired reputation, we may instance, in poetry, dramatic art, and fiction, Victor Hugo, the greatest of living French poets, Alfred de Vigny, Frédéric Soulié, and A. Dumas the elder, one of the most prolific of novel-writers, among whose most popular works are—*Les Trois Mousquetaires*, *Le Comte de Monte Christo*, *Le Collier de la Reine*, &c. He published ample reminiscences of his various travels and personal adventures in *Le Caucase*, *Voyage*, *Les Mémoires d'Horace*, *Mémoires de Garibaldi*, the successive volumes of his own *Mémoires*, &c. The catalogue of his writings is scarcely conceivable for its extent, numbering, it is said, above 1200 volumes. Casimir Delavigne has attempted to combine the romantic and classical schools in his *Louis XI.* *Les Enfants d'Edouard*, &c. George Sand (Madame Dudevant) is one of the most elegant writers of her country, and her works are models of style. Her *Indiana*, which appeared in 1832, inaugurated a new era of emotional novel-writing, and has had numerous imitators. Among her numerous works, the most popular are *Lélia*, *Mauprat*, *Andr*, *Consuelo*, and the numerous pieces which she subsequently wrote for the stage, such as *François le Champi*, *Marquis de Villemer*, &c. *Les Mystères de Paris*, and *Le Juif Errant*, which depict the concealed miseries and depravities of social life, quickly brought their author, Eugène Sue, into notice.

The tendency to materialism and sensualism, which characterizes the works of the two last-named writers, is more or less perceptible in all belonging to their age in France. The few artistic and good historical novels that have appeared have not met with the success they deserved. Among other recent writers of fiction, we may especially instance Balzac; A. de Masset, with his unrivalled richness of fancy, and melody of speech; Jules Sandeau, with whom Madame Dudevant wrote in conjunction; the historian Merimée; Théophile Gautier; Paul de Kock; the literary partners, Erckmann-Chatrian; Edmond About; and Dumas the younger, who has latterly devoted himself mainly to writing for the theater, which still absorbs much of the talent of France (as in Sardou's case). Till recently, few names in the domain of poetry, beyond those of Béranger, Lamartine, Victor Hugo, De Vigny, Sainte Beuve, and De Musset, were much known out of France: Gautier and De Banville, lyrists of the romantic school, have of late obtained a favorable hearing in many lands; and De Lisle is recognized as the head of a small but popular modern school. History is undoubtedly the most successful branch of modern French literature. Among those who have gained for themselves a world-wide reputation in this department of research, we would instance Barante, whose early work, *L'Histoire des Ducs de Bourgogne*, has been followed by his able histories of the *Convention* and *Directory*. Guizot has shown inde-

fatigable powers of research and a philosophic power of generalization in a great number of works, among which the first rank may be awarded to his *Essais sur l'Histoire de France*, and *L'Histoire de la Civilisation en Europe*. Thierry, in his *Lettres sur l'Histoire de France*, and *L'Histoire de la Conquête de l'Angleterre par les Normans*, displays great powers of narration and aptitude for theoretic criticism, perhaps more imaginative than sagacious. Sismondi has shown great research and profound knowledge in his somewhat diffuse History. The late President A. Thiers has devoted his learning, industry, and powers of delineation to the exposition of the revolutionary and imperial phases of French government. Louis Blanc, in his *Histoire de Dix Ans*, gives one of the most vivid pictures of contemporary history that we possess. Lamartine, who carries his poetic inspirations and enthusiastic temperament with him into his historical researches, presents magnificent but not perfectly trustworthy pictures of history in his *Histoire des Girondins*, *Histoire des Constituents*, and *Histoire de la Restauration*. Vilemain, although better known for his history of literature, is yet to be classed among historians. Michelet is known as the brilliant author of the *Histoire de France*, Martin and Taine, both recently admitted members of the Académie, may close the list.

There is no department of the moral and physical sciences that has not been enriched and elucidated by the labors of French savans. Among the great scientific writers of modern France, we may instance in metaphysics and political economy, Victor Cousin, Jouffroy, Simon, and Lamennais, whose eloquent defence of spiritualistic and religious principles reacted strongly against the materialism to which French philosophy had long been addicted; while socialism has found powerful advocates in Comte, St. Simon, Fourier, and Leroux. Chevalier, De Tocqueville, Bonald, and Laferrière, are known for their able and philosophic exposition of the jurisprudence of nations, and the social and political condition of democracy in the new and old world.

In philology and ancient history, Champollion, Sylvestre de Sacy, Renan, Renusat, and Stanislas Julien, by their profound researches into Egyptian hieroglyphics and Semitic literature, have thrown new light on the origin of races and languages. In mathematics D'Alembert, Laplace, Lagrange, Biot, Ampère, and Arago stand unrivalled. In natural history, and its kindred sciences, among a host of great French discoverers, we can only instance a few of the more distinguished, as Cuvier, Geoffroy and Isidore St. Hilaire, Blainville, Jussieu, D'Orbigny, Haüy, Gay-Lussac, Elie de Beaumont, Milne-Edwards, and Brongniart, whose painstaking and important services in the cause of science have identified their names with the triumphs of physical research.

No country has ever produced a greater number of elegant essayists and literary critics than France, and no language seems to lend itself more readily than French to a concise and graceful, yet forcible style of epigrammatic writing, and few admit of more idiomatic terseness, or greater polish. See Saintsbury's *Short History of French Literature* (1882); the *Histoire de la Litt. Française*, by Nisard (1846), and that by Gêruzeux (1852); Vilemain, *Tableau de la Littér. au Moyen Âge* (1857); Demogeot, *Hist. de la Littér. Franç.* (1857); Littré's *Histoire de la Langue Française* (1867); Gidel's *Histoire de la Littérature Française* (1875); *La Littérature Française*, Staaff (1869—1873); *History of French Literature*, by H. Van Laun, (1877—1879).

FRENCH POLISHING, the name given to the now common method of coating wood with a fine smooth surface or varnish of gum-lac. Gum-lac is easily soluble in spirits of wine, methylated spirits, or wood-naphtha, and a varnish is thus produced; but if it be applied simply with a brush, as copal, mastic, and most other varnishes are applied, the result is a very rough and broken surface, instead of a smooth continuous polish. To obtain (this with a lac-varnish on wood, it is necessary to apply a very small quantity at once, and to rub it continuously until it dries. If a dry rubber be used, the lac sticks to it, and it is dragged from the wood. An oiled rubber is therefore used, and the oil should be a drying oil, such as linseed. Various kinds of rubbers are used; such as a ball of wood covered with rag, a small roll of cloth with the edges downwards, and likewise covered with rag. The varnish and oil may be mixed together in a bottle, shaken up when used, and a little poured upon the rubber; or a simple solution of shell-lac may be used, and some of this laid upon an oiled rubber. Several successive coats and rubbings are required, and some skill is necessary, in order to produce a good surface.

The following are some receipts for French polish for mahogany; they might be multiplied to a great extent, for they should be modified according to the kind of wood to which they are applied, and the mode of applying them: 1. 5 oz. of pale shell-lac, dissolved in 1 pint of wood-naphtha, or methylated spirit, or spirits of wine. 2. 5 oz. of pale shell-lac, 1 oz. gum sandarac, 1 pint spirit. 3. 1½ lb. pale shell-lac, ¼ lb. mastic, 2 quarts spirit. 4. Shell-lac, 6 oz.; spirit or naphtha, 1 pint; linseed oil, ½ pint. The last is the most easy to apply; it requires no oil on the rubber,

and is a very good domestic polish for restoring furniture, if properly applied by careful and continuous rubbing.

FRENCH PROTESTANT CHURCH. See **HUGUENOTS.**

FRENCH RIVER, a stream of Upper Canada, empties Lake Nipissing into Lake Huron, entering Georgian Bay in lat. 45° 53' N., and long. 81° 5' W. It has a rapid course of about sixty miles; and, towards its mouth, is so uniform in breadth and depth, as to resemble an artificial cut through bare rock. It forms part of the route by which canoes, preferring the Ottawa to the St. Lawrence, pass from Montreal to the Red River of the north.

FRENCH SETTLEMENTS. See **PONDICHERRY.**

FRÉRON, ÉLIE CATHERINE, a French writer, was born at Quimper in 1719, educated under the Jesuits at the college of Louis le Grand, and first acquired a reputation by his publication of a critical journal in 1746. This journal appeared under the curious title, *Lettres de Madame la Comtesse de ****. It was suppressed in 1749, but virtually re-appeared as *Lettres sur quelques Ecrits de ce Temps* (13 vols., 1749—1754), and was again continued under the title of *Année Littéraire* (1754—1776). F. exhibited the most intense bitterness against his leading contemporaries. A worshiper of the age of Louis XIV., he hated and satirized the levelling philosophy of his times. Voltaire was the special object of his aversion, and that sensitive scoffer was deeply galled by the weekly diatribes of his antagonist. The names of Voltaire and F. are inseparably, though not amicably, conjoined in the history of literature. F. was often right in his criticisms and in the accusations which he brought against his adversaries, but opinion in France in the 18th c. was swayed by epigrams, and F. fell a victim to the animosity of the wits. He died of grief, March 10, 1776.—**LOUIS STANISLAS FRÉRON**, a son of the former, was born in Paris in 1765, played a somewhat prominent part in the melodrama of the French Revolution, and in 1802 was sent as sub-prefect to the island of St. Domingo, by the First Consul, but died two months after his arrival.

FRESCO, FRESCO-PAINTING, or PAINTING IN FRESCO, the term applied to paintings executed upon plaster while it is still wet or fresh (Ital., *fresco*). Many celebrated artists and well-known writers have maintained that fresco is the only way in which the highest efforts in art should be embodied. A very large proportion of the best works of the Italian schools, particularly those of Rome and Florence, are done in this manner; and during the present century it has been revived, and many of the chief paintings of the modern German school are executed in fresco. The practice has to some extent been introduced into Britain, and certain works of that kind have been executed in the new Houses of Parliament. Munich has been the chief home of this revived art.

Before noticing more particularly the various properties claimed for fresco-painting, it is proper first to describe the process. A cartoon or drawing on paper is first made of the subject. This must be executed with a correct outline, and the shading and effect fully made out. The finished cartoon may either be of the same size as the intended fresco, or it may be done on a smaller scale; but, at all events, an outline of the same size as the fresco-painting is necessary. When the finished cartoon is made the same size as the fresco, it is generally executed in black and white, with chalk or charcoal, but it is essential to have also a careful study of the subject in colors, and this is in most cases done on a small scale. The colors used are mostly earths or minerals, as few others will stand the action of lime: these are ground and applied with pure water. The ground to be painted on is the last or smooth coating of plaster that is laid over the rough plaster-work with which walls are prepared. This last coating, or ground, or rather as much of it as the artist calculates on being able to cover in one day, is laid on immediately before he commences work. The surface is wet, but firm and smooth; the tracing is laid over the portion prepared, and the artist, with a point of hard wood or bone, goes over the lines of the tracing, and slightly indents them on the plaster. He then proceeds with his work, the finished cartoon and colored sketch being hung or placed near him for his guidance. After his day's work is over, any portion of the plaster that has not been painted on, or that may remain beyond or at the edge of his work, is cut away; and next day, when the painter is ready to commence work, the plasterer is at hand, and joins closely another portion of plaster to the edge of the portion painted on the previous day, which, when cut, had been slightly sloped. The lime, in drying, throws out a kind of crystal surface, which protects the color, and imparts a degree of clearness much superior to, and easily distinguishable from, that of a work in tempera or size paint. This process, although apparently simple, nevertheless requires great dexterity and certainty of hand; for the surface of the plaster is delicate, and must not be overworked, besides, the lime only imbibes a certain quantity of additional moisture in the form of liquid colors, after which it loses its crystallizing quality, and the surface,

or a portion of it, becomes what painters call rotten. Many frescoes are defective in this way. It is only after the lime has dried that such flaws are discovered; the proper plan, in such a case, is to cut away the defective portion, have fresh plaster laid on, and do the work over again. But the flaws are too often retouched with tempera or size colors; and though they may escape notice for a time, the parts touched will change or come off in the course of a few years. Another difficulty in fresco is, that the colors become much lighter after the plaster dries, and for this allowance must be made. However, by practice, the painter may soon get over this difficulty; and he can test the difference between the color as wet and as dry, by putting a touch on a piece of tumber he has generally at hand, which instantly dries the color, and shows as it will be when the lime has dried.

The pre-eminence claimed for fresco-painting is founded on—1. The quality it possesses of clearness and exhibiting colors in a pure and bright state. The surface not being dry and dull, as tempera or size color, nor glossy like oil-paintings, is capable of being favorably viewed from any point. 2. Its durability—many frescoes being painted on arcades or the cloisters of churches open on one side, some on the fronts of houses entirely exposed in the open air. 3. The skill and dexterity required in execution—retouching not being admissible, nor those various appliances of glazing over painting, &c., available in working with oil-colors; all which circumstances compel the fresco-painter to confine his energy more to the subject and design, than to the mechanical qualities so much sought after by painters in oil. The frescoes of M. Angelo in the Sistine Chapel, by Raphael in the stanze of the Vatican, and those in the cupola of the cathedral of Parma by Correggio, are pointed to by the advocates of this mode of art as settling the question.

But, on the other side, it may be said—1. Though a certain degree of clearness and purity of color results from fresco, it is deficient in depth and richness. The absence of glossiness is no doubt an advantage in the case of mural-painting with reference to architectural decoration; but to a considerable extent this difficulty can be obviated in the case of painting in oil; and Delaroche's great picture of the Hemicycle in the Beaux Arts in Paris, which is in oil, is not objectionable on that ground—indeed, many mistake it for fresco. 2. No doubt, in fresco, the colors are not liable to change much, if the work be executed in pure fresco, and not retouched; but, generally speaking, the surface is fragile, and easily broken or scratched, and there is no way of mending it but by retouching with tempera colors; and if that be extensively done, its nature is altered, and it becomes a picture in size and colors. The 'Madonna de Foligno,' 'Madonna di San Sisto,' 'Spasalizia,' and other celebrated easel-pictures by Raphael, are in much better preservation than his frescoes in the stanze of the Vatican. 3. The properties of difficulty in execution and limited range of coloring, and of technical appliances, are of a negative kind. No doubt, some painters have maintained that good coloring is incompatible with grand compositions; but, on the other hand, Titian's 'Entombment' in the Louvre, and Peter Martyr in Venice, among others, are referred to as rebutting such an assertion.

Mural-painting is of great antiquity: in Egypt, in the Etruscan tombs, on the walls of houses in Pompeii, and in the catacombs, there are various remains of paintings which are generally considered to be frescoes; those in Pompeii, in particular, are remarkable for grandeur and purity of style in design and drawing; but they are executed in a slight and free manner, and on this account, and from the same or nearly similar subjects being often found repeated, are supposed to be copies by house-decorators of celebrated paintings that were preserved in temples or palaces at Rome. Whether these were frescoes painted on the walls or movable pictures, is matter of dispute. 'The Greeks preferred movable pictures, which could be taken away in case of fire, or sold if necessary.'—Wilkinson on *Egyptian and Greek Paintings*. Pliny says Apelles never painted on walls; and various pictures of immense value are stated to have been taken from Greece to Rome.

On the whole, it may be assumed as an opinion that has long been generally adopted, that where painting is to be combined with architecture, fresco is the style that assimilates most with it. On the other hand, the fact of Delaroche having so successfully executed in the Beaux Arts a work in oil, which by size and subject was so well adapted for fresco, and the circumstance of the adoption lately in Germany, and by the artists in our Houses of Parliament, of stereochromic painting (see below) in place of fresco—a method by which certain defects in the process of fresco-painting are said to be obviated—mitigate against the soundness of some of the opinions hitherto adopted as to the advantages ascribed to fresco-painting.

Fresco Secco is a spurious kind of fresco, much used in Italy in ordinary house-decoration. The colors, mixed in water, are laid on the wall after the plaster is dry, and adhere in a certain degree by absorption, the hard or glassy surface which forms on plaster

after it dries being first removed by pumice or otherwise. Pictures executed in this manner look coarse and dry, or rotten, and are in every way inferior to pure fresco.

Stereochromic Painting (Gr. *stereos*, firm, and *chroma*, color).—The ordinary process of fresco secco, however, has lately assumed very great importance from a discovery by the late Dr. J. R. von Fuchs of what is called water-glass (see FUCHS'S SOLUBLE GLASS), which, being passed over the surface of a work executed in fresco secco, imparts much brilliancy, and fixes and gives great durability to the colors; this method is styled stereochromic painting, and has been extensively practised in Berlin by Kaulbach and other eminent German artists. The late Prince Albert was so much impressed by the bearing which this discovery would have on the art of mural-painting, that he translated from the German a pamphlet describing the 'manufacture, properties, and application of water-glass (soluble alkaline silicate), including a process of stereochromic painting,' and printed it for private circulation. Mr. MacIse, R.A., made use of this new style of art in executing his great picture in the palace of Westminster of the 'Meeting of Wellington and Blücher at Waterloo.'

FRESHWATER HERRING. See COREGONUS.

FRESHWATER MUSCLE, a popular name common to a whole family of lamellibranchiate molluscs, *Unionidæ* (sometimes called *Naiadæ*), allied to muscles (*Mytilidæ*), but having a much larger foot, which does not generally produce a Byssus (q. v.), except in a very young state of the animal. All the known molluscs of this family are inhabitants of fresh water, some of them being found in still, and some in running waters. A few species are European; but it is in North America that they chiefly abound, its lakes and rivers producing many species. They crawl about by means of the foot; many of them generally live immersed in mud. They are supposed to feed on animalcules, and on decomposed animal and vegetable matter. The epidermis of many is brilliantly colored, and the inside of the shell is lined with a brilliantly and variously colored nacre, so abundant as to be sometimes used for mother-of-pearl. Pearls are sometimes produced. There are four British species, of which one, *Anodon cygneus*, attaining a size of 2½ inches long by 6 broad, is common in lakes, ponds, and muddy rivers. It is very variable in the thickness of the shell and in other particulars. The hinge is toothless.

Two species are confined chiefly to the south and east of England; the fourth (*Unio* or *Alasmodon margaritifera*, *Mya margaritifera* of Linnæus) inhabits the rivers of mountainous and hilly districts with a rocky bed, and has long been celebrated for the pearls which it produces. It is about 2½ inches long by 5 broad, and has a thick blackish-brown shell, with a toothed hinge. It is the most northern European species, and is found in the rivers of Norway and Sweden. The pearls of the British rivers were famous among the ancient Romans; and Suetonius represents them as having formed an inducement for Caesar's expedition. Some of the rivers of Wales, the north-west of England and Scotland,

Freshwater Muscle (*Alasmodon margaritifera*);

have at various times produced beautiful and valuable pearls. In several of the rivers and lochs in Perthshire, muscle-gathering is quite a trade, and the pearls found form the means of subsistence to many families. A pearl from the Conway, presented by Sir Richard Wynn to the queen of Charles II., is among the ornaments of the British crown. Large and fine pearls have also been procured from rivers of Tyrone and Donegal.

FRESHWATER STRATA are so named from their supposed origin. This can be easily determined from an examination of the contained fossils. Though the great proportion of aqueous rocks are of marine origin, yet freshwater strata are occasionally met with. The yellow sandstones of the Old Red or Lower Carboniferous period are freshwater beds, as are also the Burdie House limestone in the Edinburgh coal-field, the Pubeck beds in the Oolite, the Wealden beds in the Chalk, and the Hempstead and other beds in the Eocene period.

FRESNEL, AUGUSTIN JEAN, a French physicist, was born at Broglie, in the department of Eure, 10th May 1788, educated at Caen at the Ecole Polytechnique, and finally at the Ecole des Ponts et Chaussées. On the completion of his studies, he was sent as government engineer to La Vendée, and afterwards to the department of Drôme, where he remained till March 1815. On the return of Napoleon from Elba, F. offered his services to the Bourbons, but ill health prevented him from actively engaging in

military life. At the Restoration, he resumed his duties as government engineer; but in the interval he had been devoting his enforced leisure to physico-mathematical researches, particularly the polarization of light, with so much success, that although in a letter, dated 28th December 1814, we find him writing to a friend to get him some books on the subject, as he did not know what the phrase 'polarization of light meant' ('Je ne sais ce qu'on entend par la polarisation de la lumière'), yet before the completion of the following year, he ranked among the first authorities on the question. In ignorance, it is said of the labors of Young, F. demonstrated to his countrymen the error of the Newtonian theory of the propagation of light by the emission of material particles, and ably advocated the undulatory hypothesis. The result of his researches was exhibited in a memoir, crowned by the French Académie des Sciences in 1819.

Along with Arago, he investigated the action exercised by polarized rays of light on each other, and their discoveries, published in a joint memoir, confirmed his previous theory on the mode of the propagation of light. His practical application of the new theory to the improvement of the light-house system, was of incalculable value, and has quite abolished the old method of illuminating light-houses. See LIGHT-HOUSES. In 1823, F. was elected a member of the Académie des Sciences; in 1825, a member of the Royal Society of London; and in 1827, received from the same Society the Rumford medal for his discoveries concerning light and heat. He died July 14, 1827.

FRESNILLO, a mining town of Mexico, in the state of Zacatecas, 30 miles north-west from Zacatecas, on a feeder of the Santiago or Tololatlán. It has a spacious square, in the center of which is a splendid fountain. In the neighborhood are silver and copper mines, which are among the most productive in Mexico. Pop. 12,000.

FRET, a figure, in Heraldry, resembling two sticks laid saltier-wise, and interlaced with a muscle.

Fret.

Fretty.

FRETTY. When six, eight, or more pieces are represented crossing and interlacing like lattice-work, the shield is said to be fretty.

FREUDENSTADT, a town in Württemberg, and capital of a bailiwick of the same name, in the circle of the Black Forest, 40 miles south-west of Stuttgart, is situated on a rock which is washed by the Murg. It was founded in 1599 by Duke Frederic I., and peopled by Protestant refugees from Austria. It has a considerable trade in wood, cattle, and fruit. Cotton-spinning, weaving, bleaching, smith-work, especially making nails, &c., are the principal industries. The town is regularly built. It has a good market-place with arcades, and a grammar-school. The environs are beautiful, and present many interesting prospects. Pop. (1880) 6026, nearly all Protestants.

FREYJA AND FRIGGA, though spoken of in northern mythology as distinct, are originally one, and intimately associated with Freyr. Frigga, in the genealogy of the Ases (q. v.), is the supreme goddess, wife of Odin, and one of the daughters of the giant Fiögwyn, and presides over marriages. Freyja is the daughter of Niord, sister of Freyr, and goddess of love. She is drawn on a car yoked with cats; to her, deceased women go, and also the half of those that fall in battle, whence she is called Val-Freyja. In this last respect, she must be considered as signifying the Earth; but the earth is also represented by Frigga, the wife of Odin, and when Freyja seeks Odin, as Isis seeks her Osiris, this is Odin conceived as the Sun. The names also, Frigga and Freyja, are in signification almost alike, and the two are often confounded in mythology. The Anglo-Saxons and Lombards worshiped the wife of Odin as Frea. The name yet survives in Friday.

FREYR, the son of Niord, of the dynasty of the Vanagods, was adopted with his father among the Ases, who, when he got his first tooth, bestowed upon him the celestial castle Alfheim. He is the god of peace and fertility; dispenses rain and fertility; and to him prayers for a good harvest are addressed. His wife is Gerda, daughter of the giant Gymer. F. had seen her as he once ascended the lofty seat of Odin, Hlidskialf, from which everything on earth is seen. Gerda was so beautiful, that the brightness of her naked arms illuminated air and sea. Seized with violent love, F. sent Skirnir as spokesman, and for his services had to give him his good sword, which he will miss in the great final contest or eclipse of the gods. Like Freyja, he was the

patron of marriage, and probably the two were at one time conceived as united, hermaphrodite-wise. F. was held in great veneration, especially in Sweden, of which he was patron-god, and also in Iceland. His chief temple was at Upsala, where a bloody offering was yearly made to him of men and animals. His festival was at the winter solstice, the turn of the year—Yule-tide. While the god was borne round the land, all strife was laid aside. (Does the procession of the boar's-head, at Christmas-time, commemorate F., who rode on the boar, Gullinbursti, and whose symbol was the boar's-head?) The circumstance that the Saxon form of F.'s name, Fro, has been preserved in the German name of a Christian festival Fronleichnam (Corpus Christi, the Lord's body), seems to show that it had become among these peoples the abstract term for a god.

FREY'STÄDTEL, FREYSTADT, or (Hung.) **GALGOCZ**, a town of Hungary, in the circle of Neutra, 84 miles north-west from Pesth, on a height above the left bank of the Waag, opposite to Leopoldstadt. The Waag is here crossed by a long bridge. F. contains a fine castle belonging to Count Erlody, situated on a steep limestone cliff, with fine gardens. There is also a curious round tower, supposed to have been a Turkish minaret. Various articles of wood are extensively manufactured. There are important cattle-markets. Pop. (1880) 6410.

FREYTAG, GUSTAV, a dramatic poet and novelist of Germany, was born 13th July 1816, at Krenzburg, in Silesia, studied at the universities of Breslau and Berlin, and took his degree in philosophy in 1838. His first important work was a comedy, entitled *Die Brautfahrt, oder Kunz von Rosen* (Breslau, 1844). Among his other productions may be mentioned *In Breslau* (Berlin, 1845), which is a collection of small poems written in a popular style; the dramas *Die Valentine* (Leip. 1847) and *Graf Waldemar* (Leip. 1848); and the comedy entitled *Die Journalisten* (1854). An edition of his dramatic works was published at Leipzig, in 3 vols., 1848—1850. But his greatest achievement in literature is undoubtedly *Soll und Haben* (Leip. 1855), a novel of German citizen-life. It has been translated into English by Mrs. Malcolm under the title of *Debit and Credit* (1858). In 1859, F. published a new classical drama, *Die Fabier*. A series of prose pictures from German History, entitled *Neuere Bilder aus dem Leben des Deutschen Volkes* (Leip. 1862; Eng. trans. *Pictures of German Life*), followed the series, *Bilder aus der Deutschen Vergangenheit*. *Die Verlorene Handschrift* (*The Lost Manuscript*), appeared in 1864. The series of tales called *Die Ahnen* includes *Ingo und Ingerman*, *Das Nest der Zaunkönige*, *Die Brüder vom Deutschen Hause*, and *Markus König* (1876). F. has also written on the rules of the drama. In 1870, he retired from the editorship of the *Grenzboten*, which he had conducted for twenty-three years, and became the editor of a weekly magazine published at Leipzig.

FRIAR, a name common to the members of certain religious orders in the Roman Catholic Church, and generally employed in contradistinction to the name Monk and Regular Clerk (see these articles). The name friar, although from its etymology (*frère*, brother) it belongs to the members of all religious brotherhoods, yet has come to be reserved almost exclusively for the brethren of the Mendicant orders. It is applied chiefly to the four great orders, Dominicans, Franciscans, Augustinians, Carmelites, and later, to the Trinitarians, and to the various branches of these orders. The Franciscans were properly denominated 'Friars Minor' (*Fratres Minores*). The Dominicans received, in contrast, the title 'Friars Major,' which, however, was perhaps rather a sobriquet than a serious name. These several bodies of friars, too, were popularly called, from the color or other peculiarity of their habit, Grey Friars (Franciscans), Black Friars (Dominicans), White Friars (Carmelites), Crutched [or Crouched (*Cruciati*, 'crossed')] Friars (Trinitarians), so called from the cross, which was embroidered upon their habit. This is the origin of the names of the several localities in London, and other towns thus designated, to the present day. In the orders to which we refer, the friars who are in priest's orders are styled 'father.' The other members are called simply 'brother.' The vow taken by friars at profession is of the class called in the Catholic Church 'solemn,' and is held to render null and void any contract of marriage entered into by the party subsequently to his religious profession.

FRIARS' BALSAM. See **BENZON**.

FRICTION. When one body rubs against another as it moves, a certain force is felt to resist the motion. This resistance is called *friction*. As a considerable proportion of the motive-power in all operations is spent in overcoming the friction of the parts of the machine upon one another, and is thus lost for the useful work, it is of great importance to understand the nature of this obstructive force, with a view to reduce it to the least possible amount. Accordingly, a great many careful experiments have been made on this subject, and the result is a number of precise and valuable facts or laws regarding friction, which are

now considered certain and reliable. The more important may be thus stated and illustrated.

When a block of oak—say a cubic foot, which weighs about 60 lbs.—is placed on a horizontal table of cast iron, the two surfaces being flat and smooth, it requires a force of nearly $\frac{1}{2}$ the weight of the block, or 24 lbs., pulling horizontally, to make it slide along the table. This measures the friction between the two surfaces. Another block of the same size and shape laid on the same table, would require the same force to draw it; and if the two were laid side by side, and fastened together so as to become one block, it would evidently require double the force or 48 lbs., to draw the double block; the amount of the friction being thus still $\frac{1}{2}$ of the weight, or of the pressure between the two surfaces. But suppose that, instead of being laid side by side, the second block were laid on the top of the first, what is to be expected? Here the weight is double as before, but the extent of rubbing surface remains unaltered; it would be natural, therefore, to expect that this would make a difference, and that, though the friction would, of course, be increased, the increase would be less than in the former case.

Experiment, however, shows that there is no difference, and that the friction is just double in both cases. In short, the unexpected and important fact is established, that, *within certain limits, the friction of any two surfaces increases in proportion to the force with which they are pressed together, and is wholly independent of the extent of the surfaces in contact.*

The amount of friction between two bodies is thus a constant fraction or proportion of the force with which they are pressed against each other. This fraction differs for the different kinds of surfaces. Thus, between oak and cast iron, it is, as already stated, about $\frac{1}{2}$, or more exactly, .38; for wrought iron on wrought iron (we speak at present of dry surfaces, without grease or nunguent of any kind), it is .44; for brass upon cast iron, .22. This constant fraction (expressing the proportion between the pressure of two surfaces and their friction) is called the *coefficient of friction* for these two surfaces.

Another way of illustrating this law of friction is the following, which has an important bearing on the erection of structures, and on mechanics in general. Suppose a slab AB, in contact with another slab CD, of the same or of different material; and that a force PQ presses on AB obliquely. Let QR be the perpendicular to the two surfaces, and draw PR, PS parallel to AB and QR, thus resolving the force PQ into two forces, one, PS, pressing AB against CD, the other, PR or SQ, tending to make AB slide towards C. It will clearly depend upon the strength of friction between AB and CD, how far the force PQ may be made to decline from the perpendicular without actually causing the one body to slide on the other. Suppose that when the pushing force is brought into the position P'Q, AB is just ready to slip on CD, and that it is a case of oak upon iron; then, since P'S' or R'Q is the force pressing the surfaces together, and P'R' or S'Q the force tending to produce motion, PR' will be $\frac{1}{2}$ of P'Q. The angle PQR is called the *limiting angle of resistance* of the two surfaces AB, CD; for so long as the direction of the pressure PQ is within that angle, the friction of the surfaces will sustain it, but if the obliquity is greater, the surfaces will slip. This is true, independently of the extent of the surfaces in contact; and also of the amount of the pressure; for the stability depends upon the proportion of PR to PQ, and that is the same, whatever is the length of PQ, so long as its inclination is the same.

If the slab CD were tilted up, so as to form an inclined plane, until AB were on the point of sliding, the angle of inclination would be found to be equal to the limiting angle of resistance RQP'.

Knowing the coefficient of friction of any two substances, their limiting angle of resistance is easily found. *Example*.—The coefficient of brick upon hard limestone is .60; required the limiting angle. Take a line QR' of any convenient length, raise a perpendicular R'P' equal to $\frac{60}{100}$ of QR', and join QP'; RQP' is the angle required: if measured, it would be found to be about 31°. In any structure, then, the obliquity of the thrust between two surfaces of these materials must always be considerably within this limit in order to be safe.

The *friction of quiescence*, that is, the resistance to the commencement of motion, is greater than the resistance to its continuance; and the more so if the surfaces have been a considerable time in contact. But the slightest shock or jar is sufficient to destroy this cohesion, or whatever it is that constitutes the peculiar initial resistance; so that it is only the constant and regular friction of motion that is of much consequence in practice.

Friction is very much diminished by the use of grease or unguents. The coefficient of wrought iron upon oak, which, in the

dry state, is .49, is reduced by the application of water to .26, and by dry soap to .21. The result of experiments on this subject is stated to be, 'that with the unguents, hog's-lard and olive-oil, interposed in a continuance stratum between them, surfaces of wood on metal, wood on wood, metal on wood, and metal on metal (when in motion), have all of them very nearly the same coefficient of friction, the value of that coefficient being in all cases included between .07 and .08.' Tallow gives the same coefficient as the other unguents, except in the case of metals upon metals, in which the coefficient rises to .10. In the case of wood on wood, black-lead is frequently employed for the same purpose. The most important fact, perhaps, and one that could hardly have been anticipated before experiment, is, *that the friction of motion is wholly independent of the velocity of the motion.*

The resistance to the motion of a wheeled carriage proceeds from two sources; the friction of the axle, and the inequalities of the road. The resistance of friction to the turning of a shaft in its bearings, or of an axle in its box, has evidently the greater leverage, the thicker the journal or the axle is; the axle of wheels are accordingly made as small as is consistent with the required strength. The resistance that occurs between the circumference of the wheel and the road, constitutes what is called *rolling friction*. There are on all roads, to a greater or less extent, visible rigid prominences, such as small stones, in passing over which the wheel and the load resting on it have to be lifted up against gravity. But even were these wanting, the hardest road yields, and allows the wheel to sink to a certain depth below its surface; so that in front of the wheel there is always an eminence or obstacle, which it is at every instant surmounting and crushing down. This is the case even on iron rails, though of course to a much less extent than on any other road. Now for overcoming this resistance, it can be shown, on the principle of the lever, that a large wheel has the advantage over a small one; and by numerous experiments, the fact has been fully established that, on horizontal roads of uniform quality and material, *the traction varies directly as the load, and inversely as the radius of the wheel.*

The best direction of traction in a two-wheeled carriage is not parallel to the road, but at a slight inclination upward, in proportion to the depth to which the wheel sinks in the road.

On a perfectly good and level macadamized road, the traction of a cart is found to be $\frac{1}{30}$ of the load; that is, to draw a ton, the horse requires to pull with a force equal to 75 lbs. On a railway, the traction is reduced to $\frac{1}{325}$ of the load, or to 8 lbs. per ton.

While friction thus acts as an obstruction to motion, and wastes a portion of the motive-power, it has also important uses. It is, in fact, an indispensable condition, no less than gravity, in the stability of every structure, and in every mechanical motion on the earth's surface. How essential it is to our own movements, we experience when we try to walk on ice. Even on ice there is still considerable friction, so that one foot can be slightly advanced before the other; were it altogether annihilated, we could not stir a fraction of an inch, even supposing we could stand upright. Without friction, a ladder could not be planted against a wall, unless there were a hole in the ground to retain the foot. In short, no oblique pressure of any kind could be sustained. The advantage of railways consists chiefly in the diminution of friction; but were this diminution carried much further, there could be no motion whatever, at least by means of locomotives. Without considerable friction, the driving-wheels of the locomotive would slide round on the rails without advancing; and this sometimes happens, when particular states of the weather render the rails as if they were greased.

The force of friction is often directly employed in mechanics. It is used, for instance, to communicate motion by means of belts, chains, &c. It is the force that holds a knot. It is specially useful when a machine, with great momentum, has to be checked or arrested in its motion. The best example of this is the *break* used on railways. By means of a system of levers, blocks of wood are made to press against the circumference of a number of the carriage-wheels; and thus the momentum of a train weighing hundreds of tons, and moving with a velocity of perhaps 50 miles an hour, is gradually destroyed in a wonderfully short space of time.

Friction-wheels are employed to diminish the friction of axles on their supports. Two wheels, of large circumference in proportion to their weight, are placed close together, parallel to each other, and so that the one seems to overlap the half of the other; in the notch thus formed by the upper circumferences of the wheels one end of the axle rests; a similar arrangement being made for the other end. The friction, which formerly acted directly on the axle, is by this arrangement referred to the axles of the friction-wheels, and is, by the laws of mechanics, reduced in the ratio of the circumference of the friction-wheel to the circumference of its axle. In order to render the friction of the friction-wheels themselves the least possible, they are made as light and as large as is practicable.

FRIEDEBERG, a walled town of Prussia, in the province of Brandenburg, 56 miles north-east from Frankfurt, on the Peza. Around it are several lakes. It has woole manufactures and tanneries, and some trade in cattle. Pop. (1880) 6381.

FRIEDLAND, a small town of East Prussia, in the circle of Königsberg, situated on the left bank of the Alle, 26 miles south-east of Königsberg, in lat. 54° 26' N, and long 21° E. Pop. (1880) 3366, who are employed in linen-weaving. F. has been rendered famous by the victory obtained there by Napoleon, 14th June 1807, over the Russian forces under Bennigsen. The Russian general found himself unable to cope successfully with an army of 80,000 men, as his own force consisted of less than 50,000 horse and foot; and he was forced to retire after a disastrous battle. He fell back upon the town of Tilsit, on the Niemen, where the treaty between the French and Russian emperors and the king of Prussia, known as the treaty of Tilsit, was drawn up.—**FRIEDLAND** is also the name of a town in Bohemia, situated on the Wittig, near the Prussian border. It is the capital of a district or duchy of the same name, from which the famous Wallenstein (q. v.) took his title of Duke of Friedland. Pop. of the town (1869) 4482.

FRIEDLAND, VALENTINE, generally called, from his birth-place, *Trotzendorf*, and indisputably the greatest educationist of his age, was a native of Upper Lusatia, and was born 14th February 1490. After the death of his father, in 1513, he went to Leipsic, where he studied under the celebrated Peter Mosellanus and Richard Crocus, acquiring among other things a knowledge of Greek. On the dawn of the Reformation, he proceeded to Wittenberg, where he formed a close intimacy with Luther and Melancthon, and learned Hebrew from a converted Jew. In 1523, he proceeded to Goldberg, in Silesia, as rector of the gymnasium there; left after four years, but returned in 1531, and exhibited the greatest energy in improving the organization of the school. Success crowned his efforts. The gymnasium of Goldberg acquired a rare celebrity. Not only from Silesia, but also from Poland, Lithuania, Austria, Bohemia, Hungary, and Transylvania, pupils sought it in great numbers. Often more than 1000 attended at a time, who all dwelt together in buildings set apart for the purpose, and were admirably superintended and drilled. F. had a most wonderful belief in the efficacy of knowledge, and, in particular, placed so high a value on clearness of thought and expression, that he was wont to affirm that only rogues were unintelligible. He died 26th April 1556. See the biographies by Pinzger (1825) and Löschke (1856).

FRIENDLY ISLANDS, as distinguished from the Fiji Islands (q. v.), generally reckoned a part of them, are otherwise styled the **TONGA GROUP**. They lie to the south-east of Fiji, and consist of three sub-groups, of which some 30 islands are inhabited, Tongatabu being the largest. The great majority are of coral formation; but some are volcanic, and there are several active volcanoes. The people are the most intelligent and skilful of the fair Polynesians, but are decreasing in numbers: once reckoned at 40,000, they do not now exceed 10,000. A treaty with Germany in 1876 granted a coaling-station; and a treaty with Great Britain was concluded in 1879. The F. I. were discovered by Tasman in 1643, but received their collective name from Cook. Both these navigators found the soil closely and highly cultivated, and the people apparently unprovided with arms. The climate is salubrious, but humid; earthquakes and hurricanes are frequent, but the former are not destructive. Among the products of the islands are yams, sweet-potatoes, bananas, cocoa-nuts, bread-fruit, sugar-cane, the *titi*, hog-plum, &c.; some corn also is grown. The Flora resembles that of the Fiji group; but the native animals are very few.

The F. I. were first visited by missionaries in 1797. In 1827 the work of evangelization fell into the hands of the Wesleyan Methodists, and after a lengthened and perilous struggle with the savage paganism of the inhabitants, it was crowned with success. Almost all the islanders are now Christians; great numbers can speak English, and, in addition, have learned writing, arithmetic, and geography; while the females have been taught to sew. The various islands used to be governed by independent chiefs, but nearly the whole of them are now under the rule of one chief, called King George, who is not only a Christian, but a zealous preacher of the gospel.

FRIENDLY SOCIETIES. The uncertainties of human life and health, and the effects of these on the well-being of those who are dependent for their subsistence on human labor, are too manifest not to have arrested the attention of men in all ages, and to have taxed their ingenuity to guard against them. It is probable, therefore, that traces of some sort of institution, corresponding more or less closely to the friendly societies of modern Europe, might be found wherever mankind have not depended for their means of living on the spontaneous products of the soil. At all events, they had their prototypes in the cases, boxes, and chests, or kists—as they were called in Scotland and Germany—of the guilds and corporations of medieval Europe; which were funds not only for maintaining the dignity and ministering to the conviviality

of the members, but for providing for the aged and the sick. Mr. Turner finds them in Anglo-Saxon England, and, like the other institutions connected with municipal life, they probably formed part of the legacy of the Romans to the Teutonic conquerors of Europe. Friendly societies are a form of mutual insurance, and, like all insurances, they depend on the principle of substituting the certainty which attends the fortunes of large numbers of men for the uncertainty which belongs to the fortune of each. Their main objects are the securing, in virtue of a small periodical payment during health and vigor, of a weekly sum during sickness, a sum to cover funeral expenses at death, and sometimes of a pension after a certain age.

In some respects, therefore, joining a friendly society is better than becoming a depositor in a savings-bank. Sickness may come before the savings are considerable; or, if considerable, they may be melted away by a long-continued sickness; but after the first weekly payment is made to a friendly society, the member is secure of succor, at least for a time, and he has, perhaps, other advantages. It is possible, on the other hand, that a difficulty may be experienced, in certain circumstances, in keeping up the weekly or other periodical payments required, and in this case, in most societies, he altogether forfeits the expected benefits.

It is to be regretted that, of this excellent class of institutions, many are founded upon erroneous principles, or rather upon no principles at all; and it often happens, therefore, that those who trust to them are disappointed, the funds falling short before all claims are satisfied. This was at one time not to be wondered at, as no proper calculations for friendly societies existed; but such is no longer the case, sound calculations being now attainable. The most important observations on the average amount of sickness incident to human life are those made by the Highland Society, Mr. Charles Ansell, Mr. Finlaison on behalf of the government, Mr. F. G. P. Neison, and the Manchester Unity of Odd-fellows. The first two were formed on data too limited to be of much value; those of the government were rendered practically worthless by an arbitrary definition of sickness, which made them uncertain for youth and maturity, and deprived them of all authority in reference to old age. The calculations of Mr. Neison and the Odd-fellows are based on by far the greatest number of cases, and though investigated by the former in relation to the five years ending 1840, and by the latter in relation to a period precisely twenty years later, they corroborate each other almost completely. We give the estimate arrived at by Mr. Neison of 'sickness experienced in *weeks* in passing through different periods of life: 20 to 30, 8·7; 30 to 40, 9·9; 40 to 50, 14·8; 50 to 60, 27·1; 60 to 65, 26·6; 65 to 70, 50·7; 70 to 75, 84·9; 75 to 80, 120·5.

One great mistake in the formation of friendly societies is to assume that each member should pay an equal sum, whatever his age may be. This is unjust to the younger members, who are less likely to become burdensome to the funds than the middle-aged; and, indeed, there is a rising scale of probability of sickness throughout all the years of a man's life. It is, however, well to remember that as sickness varies more considerably than mortality with the salubrity of the localities inhabited and the occupations of the members, no absolute reliance can be placed on published averages. All of them, however, agree in this, that *increase of years is attended by increased liability to sickness*. Now, a rightly constituted friendly society is bound to take this circumstance into account. To admit all ages at an equal payment, is clearly making the younger members pay for the elder.

Another great error in the constitution of benefit societies is in making them for a year only. These *yearly societies* are to be found in almost every colliery in the north of England, and are popular among the less intelligent of the people. The objects are generally a fund for sickness and funeral expenses, a deposit fund, and sometimes a loan bank.

Towards the first, there is perhaps a weekly payment of two-pence or threepence, together with the interest arising from the loan of money to the members. Towards the deposit fund there is a payment ranging generally from sixpence to two shillings, the accumulations being received back when the society closes. The money deposited is employed in making loans to such of the members as desire such accommodation, within the amount of their several entire deposits for the year, one penny per pound per month being charged by way of interest. The surplus, if any, of the twopences and interest, after sick and funeral money, books, and other necessities are paid, is divided amongst those members who may be clear of the books at the close of the society. In some instances, only three-fourths of the funds are divided, and the members commence another year with the balance, but this only happens when they are all in good health. Nothing of the kind would occur if one or more of the number were likely to suffer more than the ordinary rate of sickness. Then the healthy members join other societies, and leave the sick to take care of themselves. In any case they are so left at the end of the year, as no society will receive them. Yearly societies are, indeed, in every point of view a most objectionable class of institutions,

to which working-people would never resort except through ignorance.

A well-constituted friendly society involves, in the first place, the principle of payments appropriate to particular ages, as no other plan can be considered equitable. It stands forth before the working-classes as a permanent institution, like the life-insurance societies of the middle and upper classes, and necessarily requires its members to consider the connection they form with it as an enduring one, because its grand aim is expressly to make provision, at one period of life, for contingencies which may arise at another—for youth, in short, to endow old age. By a yearly society, a man is left at last no better than he was at first, as far as that society is concerned; but the proper friendly society contemplates his enjoying a comfortable and independent old age, from the results of his own well-bestowed earnings.

It is essential to the character of a proper benefit society that individuals be not admitted indiscriminately. To take a person in bad health, or of broken constitution, is unjust to those members who are healthy, because he is obviously more likely to be a speedy burden upon the funds. Here, as in life-insurance societies, it is necessary to admit members only upon their showing that they are of sound constitution and in good health. And it may be well to grant no benefits until after the member has been a year in the society. By these means, men are induced to enter when they are hale and well, instead of postponing the step until they have a pressing need for assistance, when their endeavor to get into a benefit society becomes little else than a fraud.

Under the sanction of government, tables have been formed by Mr. John Tidd Pratt, late registrar of friendly societies in England, and by Dr. Farr, the actuary of the English registrar-general. The former, together with useful instructions in the book-keeping of friendly societies, are embodied in the reports by Mr. Pratt, printed by order of the House of Commons for the years 1856—1857; and the latter, together with a masterly essay on the mathematical treatment of the subject, are contained in the twelfth report of the registrar-general.

On the imperative necessity of acting on correct tables for such a purpose, it would be superfluous to dwell; and the necessity of identifying the rates of any society with such responsible authority is the more apparent, as we are told by Mr. Pratt that 'although the registrar certifies to the *legality* of the rules of a friendly society, it does not follow as a necessary consequence that the constitution of the society is based on good principles, or that the rates of payment are sufficient in amount to guarantee the promised benefits and allowances.' In fact, there are large numbers of insolvent societies whose rules have been certified in the most regular manner. It cannot be too much insisted upon that the registrar's certificate is absolutely worthless as a guarantee of safety.

We have an idea of a benefit society in its simplest form, if we suppose a hundred men, of 35 years of age, to associate, and make such a payment at first as may be sure to afford each man that shall fall sick during the ensuing year one shilling a day during the term of his sickness. Taking, for the sake of illustration, Mr. Neison's Tables, we find that, amongst such a body of men, there will be nearly 100 weeks of illness in the course of the year. This, multiplied by 7, gives the whole sum required, £35 or even seven shillings each, which, less by a small sum for interest, will accordingly be the entry-money of each man. A society of individuals of different ages, each paying the sum which would in like manner be found proper to his age, would be quite as sound in principle as on the above simple scheme. It is only a step further to equalize each man's annual payments over the whole period during which he undertakes to be a paying member.

A point for consideration, however, is the rate at which the funds of the societies may be improved. In many cases, it is best to rest content with depositing the money in the funds or the savings-banks, in which case they are sure to obtain for it interest at a rate of not less than £3, 0s. 10d, per cent. per annum, or twopence per cent. per day. Some of these societies have sums invested with the Commissioners for the Reduction of the National Debt, at threepence and twopence-half-penny per cent. per day. Many of them invest with local building societies, some in corporation debentures, and in many other ways which afford a better rate of interest with safety; and the tendency to abandon the old routine of merely savings-bank deposit seems rapidly and generally growing.

By the act 27 and 28 Vict. c. 43, government gave to the working-classes an opportunity of effecting small life-insurances, or of purchasing immediate or deferred monthly allowances or annuities, in a manner absolutely free from risk, as the credit of the nation itself is pledged to meet the obligation purchased by the subscriptions or payments of the contributor. A great number of people have availed themselves of the new facilities, but it is probable that very many more would have done so had the scale begun at a lower and been continued to a higher point. At present, no life can be insured for less than £20, or more than £100.

Now, many people are willing enough to insure for as much as will cover their funeral expenses, say for £10, who would not be disposed to make further provision for their families. This class, and it is not a small one, is practically excluded from the benefit of the government system, and it would be well, in future legislation, to reduce the minimum to at least half its present amount. At the same time, the maximum might be safely increased to £200 without interfering with the legitimate business of life-assurance companies.

These government insurances are effected through the agency of the Post-office. A list of offices authorized to act may be obtained at any post-office, and at the places so authorized all necessary information and forms of proposal may be had. There also, when filled up, the forms of proposal may be delivered. The premiums charged vary with the age, but not with the sex, of the person to be insured, and the mode in which they are to be paid. For example, the life of a man or woman in his or her 30th year may be insured for £100 :

By a single payment of	£43	3	7
By an annual payment throughout life of	2	6	7
By a quarterly payment throughout life of	0	13	0
By a monthly payment throughout life of	0	4	4
By a fortnightly payment throughout life of	0	2	2
By an annual payment until the age of 60 of	2	13	10
By a quarterly payment until the age of 60 of	0	15	0
By a monthly payment until the age of 60 of	0	5	0
By a fortnightly payment of	0	2	6

Smaller sums may be insured by proportionate payments, but no one payment must be less than two shillings.

If after five years' payments the insurer desires, or is compelled by circumstances, to discontinue his insurance, a portion of the premiums, not being less than one-third, will be returned to him.

The sums charged for the purchase of *immediate* annuities vary with the *age and sex* of the person on whose life the annuity is to depend. Thus a man aged 65 can purchase an *immediate* annuity of £10, payable half-yearly, for £88, 18s. 4d.; a woman of the same age can purchase a like annuity for £103, 16s. 8d. A man aged 70 can purchase an *immediate* annuity of £10, payable half-yearly, for £73, 3s. 4d.; a woman of the same age can purchase a like annuity for £84, 19s. 2d.

The sums charged for the purchase of *deferred* annuities, or *deferred* monthly allowances, also vary with the *age and sex* of the annuitant, with the number of years which are to pass before the commencement of the annuity, and with the conditions of the contract as to the mode of purchase, mode of payment, and return or non-return of purchase-money.

When no part of the purchase-money is to be returned, a man aged 30 may purchase a deferred annuity of £10, to commence on his reaching the age of 60, and to be payable half-yearly, either by an immediate payment of £24, 3s. 4d., or by an annual payment, until he reaches the age of 60, of £1, 8s. 4d. A woman of like age may purchase a like annuity by an immediate payment of £32, 8s. 4d., or an annual payment up to 60 of £1 17s. 6d.; and a man aged 30 may purchase a deferred allowance, of £2, 7s. 8d. per month, to commence when he reaches the age of 60, by a payment until he reaches that age of 8s. per month; and a woman aged 30 may, by a like payment, purchase a deferred allowance of £1, 16s. 7d., also to commence at 60.

Purchasers of annuities are permitted to elect whether the purchase-money shall be returned to their representatives in case of death before reaching the stipulated age, or to themselves in case of desiring for any reason to withdraw from the arrangement; but for this privilege, they must pay a higher price. Thus, instead of the £24, 3s. 4d. referred to above, the purchaser at 30 of a £10 annuity, to commence at 60, would have to pay £40, 9s. 2d., and so in proportion. No annuity can exceed £50 per annum, or £4, 3s. 4d. per month, except in the case of husband and wife, who may each be insured or purchase an annuity to the full amount allowed by the act.

After many fruitless attempts at legislation, an act (38 and 39 Vict. c. 60) was passed in 1875 to consolidate and amend the law relating to friendly societies. It deals with (1) all societies which provide for the relief of members or their relatives during sickness, infirmity, old age, or widowhood, or for orphans during minority; for small insurances on occasions of birth or death; for maintenance of members in distress, or when on travel in search of employment; for endowment of members or their nominees; and for insurance of tools or other working implements up to fifteen pounds value. It is, however, provided that no society assuring annuities exceeding £50 per annum, or gross sums exceeding £200, shall be registered under the act, and that no sum exceeding £6 altogether shall be insured or paid on the death of a child under five years of age, and no sum exceeding £10 on the death of a child under ten years. It also deals with (2) cattle insurance societies, to whatever amount the insurances extend; (3) benevolent societies; (4) working-men's clubs; and (5), with certain limi-

tations, specially authorized societies, for any purpose to which, in the judgment of the Treasury, the act ought to extend. The act establishes a central office, with chief registrar and assistants, whose functions are to examine and certify rules, to prepare and circulate model forms of accounts, balance sheets and valuations; to collect and publish statistics of life and sickness, and other matters applicable to the business of friendly societies; and to construct and publish tables for the payment of sums of money at death, in sickness, old age, or other calculable contingencies. These tables, though intended for the guidance of societies, are not to be compulsory, but no society granting annuities can be registered under the act unless its tables are certified by an actuary approved by the Treasury. All societies are to have registered offices, must appoint trustees, provide for efficient audit, and furnish classified returns of receipt and expenditure annually to the registrar. Friendly societies must also, once in every five years, make a return of the sickness and mortality of their members, and prepare a valuation, either by their own valuer or the registrar, of their assets and liabilities. The nominee of a member may be paid a sum not exceeding £50 on the death of the nominator, and societies are empowered to pay a like amount to the representatives of a deceased member, without letters of administration. Minors may be members, but they are not permitted to hold office.

Societies may invest moneys in the post-office or other savings-banks, in the public funds, with the Commissioners for the Reduction of the National Debt, in the purchase of lands or the erection of buildings for their own use, and in other securities directed by their rules. Under certain circumstances, and with special guarantees, loans may be made to members on personal security. Officers are to provide sureties and render accounts, and provision is made for arbitration or summary legal jurisdiction in cases of dispute, as also for amalgamation or dissolution. The act bears abundant evidence of the care bestowed upon it in its elaborate arrangements for registration, and other precautions for the safety and success of the societies to which it relates.

FRIENDS, SOCIETY OF, the proper designation of a sect of Christians, better known as Quakers. Their founder was George Fox (q. v. for the origin of the name Quakers), born at Drayton, in Leicestershire, in 1624, who at first followed the occupation of a shoemaker, but afterwards devoted himself to the propagation of what he regarded as a more spiritual form of Christianity than prevailed in his day. In spite of severe and cruel persecutions, the Society of F. succeeded in establishing themselves both in England and America. They have, indeed, never been numerically powerful (having at no time exceeded 200,000 members); but the purity of life which from the beginning has so honorably distinguished them as a class, has unquestionably exercised a salutary influence on the public at large; while in respect to certain great questions affecting the interests of mankind such as *war and slavery*, they have beyond all doubt originated opinions and tendencies which, whether sound or erroneous, are no longer confined to themselves, but have widely leavened the mind of Christendom. For an account of the more eminent representatives of the Friends, see the biographies of BARCLAY, FOX, PENN, &c. We confine ourselves here to a brief notice of their doctrine, practice, and discipline, as it is laid down in their own publications.

Doctrine.—It is perhaps more in the *spirit* than in the *letter* of their faith that the Society of F. differ from other orthodox Christians. They themselves assert their belief in the great fundamental facts of Christianity, and even in the substantial identity of most of the doctrinal opinions which they hold with those of other evangelical denominations. The Epistle addressed by George Fox and other Friends to the governor of Barbadoes, in 1673, contains a confession of faith not differing materially from the so-called Apostles' Creed, except that it is more copiously worded, and dwells with great diffuseness on the internal work of Christ. The Declaration of Christian Doctrine given forth on behalf of the Society in 1693, expresses a belief in what is usually termed the Trinity, in the atonement made by Christ for sin, in the resurrection from the dead, and in the doctrine of a final and eternal judgment; and the Declaratory Minute of the early meeting in 1829 asserts the inspiration and divine authority of the Old and New Testament, the depravity of human nature consequent on the fall of Adam, and other characteristic doctrines of Christian orthodoxy, adding: 'Our religious Society, from its earliest establishment to the present day, has received these most important doctrines of Holy Scripture in their plain and obvious acceptation.'

It is nevertheless certain that uniformity of theological opinion cannot be predicated of the Friends, any more than of other bodies of Christians. As early as 1668, William Penn and George Whitehead held a public discussion with a clergyman of the English Church, named Vincent, in which they maintained that the

doctrine of a tri-personal God, as held by that church, was not found in the Scriptures, though in what form they accepted the doctrine themselves does not appear; and some time later, Penn published a work himself, entitled the *Sandy Foundation Shaken*, in which, among other things, he endeavored to show that the doctrines of vicarious atonement and of imputed righteousness did not rest on any scriptural foundation. But in general, the Society of F., in the expression of their belief, have avoided the technical phraseology of other Christian churches, restricting themselves with commendable modesty to the words of Scripture itself, as far as that is possible and avoiding, in particular, the knotty points of Calvinistic divinity (see Barclay's *Catechism and Confession of Faith*, published in 1673, where the answers to the questions—to avoid theological dogmatism—are taken from the Bible itself).

This habit of allowing to each individual the full freedom of the Scriptures, has, of course, rendered it all the more difficult to ascertain to what extent individual minds, among the Society, may have differed in their mode of apprehending and dogmatically explaining the facts of Christianity. Their principal distinguishing doctrine is that of the 'Light of Christ in man,' on which many of their outward peculiarities, as a religious body are grounded. The doctrine of the internal light is founded on the view of Christ given by St. John, who, in the first chapter of his gospel, describes Christ—the Eternal Logos—as the 'life' and 'light of men,' 'the true light,' 'the light that lighteth every man that cometh into the world, &c.' Barclay taught that even the heathen were illumined by this light, though they might not know—as, indeed, those who lived before Christ *could* not know—the historical Jesus in whom Christians believe. In their case, Christ was the light shining in darkness, though the darkness comprehended it not. The existence of 'natural virtue' (as orthodox theologians term it) among the heathen was denied by Barclay, who regarded all such virtue as Christian in its essence, and as proceeding from the light of Christ shining through the darkness of pagan superstition. These opinions would seem to be somewhat freer than those expressed in the General Epistle of the Society published in 1836, wherein they refuse to acknowledge 'any principle of spiritual light, life, or holiness inherent by nature in the mind of man,' and again assert, that they 'believe in no principle whatsoever of spiritual light, life, or holiness, except the influence of the Holy Spirit of God bestowed on mankind in various measures and degrees through Jesus Christ our Lord;' but, on the other hand, in a little treatise published by the Society in 1861, it is affirmed that 'the Holy Spirit has always been afforded in various measures to mankind; while stress is also laid on the statement of St. Paul, that 'the grace of God (understood by Friends to signify the 'operation of the Divine Spirit') that bringeth salvation, *hath appeared to all men;*' while another exponent of their views, Mr. T. Evans of Philadelphia (see *Cyclopædia of Religious Denominations*, Lond., Griffin & Co., 1853), states that 'God hath granted to all men, of whatsoever nation or country, a day or time of visitation, during which it is possible for them to partake of the benefits of Christ's death and be saved.'

For this end, he hath communicated to every man a measure of the light of his own Son, a measure of grace or the Holy Spirit, by which he invites, calls, exhorts, and strives with every man, in order to save him; which light or grace, as it is received, and not resisted, works the salvation of all, even of those who are ignorant of Adam's fall, and of the death and sufferings of Christ; both by bringing them to a sense of their own misery, and to be sharers in the sufferings of Christ inwardly; and by making them partakers of his resurrection, in becoming holy, pure and righteous, and recovered out of their sins.' Hence it may be safely asserted that they hold a broader (or, as others would say, a more latitudinarian) view of the Spirit's working than any other Christian church or society. In America, about the year 1827, Elias Hicks, a Friend of very remarkable powers, created a schism in the Society, by the promulgation of opinions denying the miraculous conception, divinity, and atonement of Christ, and also the authenticity and divine authority of the Holy Scriptures. About one-half the society in America adopted the views of Hicks, and are known as Hicksite Friends; their opinions, of course, are repudiated by the rest of the Society, who may be described as Orthodox Friends. The Hicksite schism thoroughly alarmed the latter, both in England and America, and a movement was begun in favor of education, of a doctrinal belief more nearly allied to that of the so-called 'Evangelical' party, and of a relaxation in the formality and discipline of the Society. The leader of this movement was Joseph John Gurney, of Norwich. This new tendency, however, excited considerable opposition among some of the Friends in America; and the consequence was a division among the Orthodox Friends themselves, and the formation of a new sect, called 'Wilburites,' after the name of their founder, John Wilbur, who are noted for their strictness with which they maintain the traditions and peculiarities of the Society. (See *Friendly Sketches in America*, by William Tallack. Lond.,

Bennett, 1862.) Some slight indications of theological differences have manifested themselves in England also.

2. *Practice*.—It is in the application of their leading doctrine of the 'internal light' that the peculiarities of the Friends are most apparent. Believing that it is the Holy Spirit, or the indwelling Christ, that alone maketh wise unto salvation, illumining the mind with true and spiritual knowledge of the deep things of God, they do not consider 'human learning' essential to a minister of the gospel, and look with distrust on the method adopted by other churches for obtaining such—viz., by formally training after a human fashion a body of youths chosen on no principle of inward fitness. They believe that the call to this work now, as of old, is 'not of men, neither by man, but by Jesus Christ, and God the Father;' and that it is bestowed irrespectively of rank, talent, learning, or sex. Consequently, they have no theological halls, professors of divinity, or classes for 'students.'

Further, as fitness for the ministry is held to be a free gift of God through the Holy Spirit, so, they argue, it ought to be freely bestowed, in support of which they adduce the precept of the Saviour—'Freely ye have received, freely give;' hence those who minister among them are not paid for their labor of love, but, on the other hand, whenever such are engaged from home in the work of the gospel, they are, in the spirit of Christian love, freely entertained, and have all their wants supplied: in short, the Friends maintain the absolutely voluntary character of religious obligations, and that Christians should do all for love, and nothing for money. It also follows from their view of a call to the work of the ministry, that women may exhort as well as men, for the 'spirit of Christ' may move them as powerfully as the other sex. The prophecy of Joel as applied by Peter is cited as authority for the preaching of women: 'On my servants and on my handmaidens I will pour out in those days of my spirit, and they shall prophesy.' They also adduce the New Testament examples of Tryphæna, Tryphosa, the beloved Persis, and other women who appear to have labored in the Gospel. Their mode of conducting public worship likewise illustrates the entireness of their dependence on the 'internal light.' In other religious bodies, the minister has a set form of worship, through which he must go, whether he feels devoutly disposed or not. This seems objectionable to the Friends, who meet and remain in silence until they believe themselves moved to speak by the Holy Ghost. Their prayers and praises are, for the most part, silent and inward. They prefer to make melody in their hearts unto God, considering such to be more spiritual than the outward service of the voice.

The doctrine of the 'internal light' has also led the Friends to reject the ordinances of Baptism and the Lord's Supper as these are observed by other Christians. They believe the Christian baptism to be a spiritual one, and not, like the Jewish and heathen baptisms, one with water; in support of which they quote, among other passages, the words of John the Baptist himself: 'I baptize you with water, but there cometh one after me who shall baptize you with the Holy Ghost and with fire.' Similarly do they regard the rite of the Eucharist: it is, say they, inward and spiritual, and consists not in any symbolic breaking of bread and drinking of wine, but in that daily communion with Christ through the Holy Spirit, and through the obedience of faith, by which the believer is nourished and strengthened. They believe that the last words of the dying Redeemer on the cross, 'It is finished,' announced the entire abolition of symbolic rites; that under the new spiritual dispensation then introduced, the necessity for such, as a means of arriving at truth, ceased, and that their place has been abundantly supplied by the Comforter, the Holy Ghost, whose office it now is to lead and guide men into all truth. The true Christian supper, according to them, is set forth in the Revelations—'Behold I stand at the door and knock: if any man hear my voice and open the door, I will come unto him, and will sup with him and he with me.' For the same reason—viz., that the teaching of the Spirit is inward and spiritual—the Friends ignore the religious observance of days and times, with the exception of the Sabbath, which some at least among them regard as of perpetual obligation.

The taking or administering of oaths is regarded by Friends as inconsistent with the command of Christ, 'swear not at all,' and with the exhortation of the apostle James—'Above all things, my brethren, swear not, neither by heaven, neither by the earth, neither by any other oath: but let your yea be yea; and your nay, nay; lest ye fall into condemnation.' They have also refused to pay tithes for the maintenance of what they hold to be a hireling ministry, believing that Christ put an end to the priesthood and ceremonial usages instituted under the Mosaic dispensation, and that he substituted none in their place. In consequence, all consistent Friends have been regularly mulcted of plate, furniture, or other goods, to the value of the amount due. The recent conversion of tithes into *rent-charge*, however, has, in the opinion of many Friends, largely removed objections to the payment to this ecclesiastical demand. In regard to the civil magistracy, while they respect and honor it, as ordained of God, they are careful to warn the members of their Society against thoughtlessly incurring its

responsibilities, involving as it does the administration of oaths, the issuing of orders and warrants in reference to ecclesiastical demands, the calling out of an armed force in cases of civil commotion, and other duties inconsistent with the peaceful principles of the Society. The Friends have likewise consistently protested against war in all its forms; and the Society has repeatedly advised members against aiding and assisting in the conveyance of soldiers, their baggage, arms, ammunition, or military stores. They regard the profession of arms and fighting, not only as diametrically opposed to the general spirit of Christ, whose advent was sung by angels in these words: 'Glory to God in the highest, and on earth, peace, good-will towards men;' but as positively forbidden by such precepts as—'Love your enemies, bless them that curse you, do good to them that hate you, and pray for them which despitefully use you and persecute you;' also, 'Resist not evil: but whosoever shall smite thee on the right cheek, turn to him the other also;' and while they acknowledge that temporary calamities may result from the adopting the principle of non-resistance, they have so strong a faith in its being essentially the dictate of divine love to the Christian heart, that they believe God, by his wise and omnipotent providence, could, and will yet make it 'mighty to the pulling down of the strongholds of iniquity.' The world, they believe, will by and by confess that the peace-makers are most truly the children of God. The efforts of the Society for the emancipation of the slaves are a part of modern British history. They may most certainly lay claim to having cultivated the moral sense of their fellow-countrymen in regard to this important question. As early as 1727, they commenced to 'censure' the traffic in slaves, as a practice 'neither commendable nor allowed,' and gradually warmed in their opposition, until the whole nation felt the glow, and entered with enthusiasm on the work of abolition. In respect to what may be called minor points, the Friends are also very scrupulous; they object to 'balls, gaming-places, horse-races, and playhouses, those nurseries of debauchery and wickedness, the burden and grief of the sober part of other societies as well as of our own.'

The Printed Epistle of the yearly meeting of 1854 contains a warning against indulging in music, especially what goes by the name of 'sacred music,' and denounces musical exhibitions, such as oratorios, as essentially a 'profanation'—the tendency of these things being, it is alleged, 'to withdraw the soul from that quiet, humble, and retired frame in which prayer and praise may be truly offered with the spirit and with the understanding also.' They object, besides, to 'the hurtful tendency of reading plays, romances, novels, and other pernicious books;' and the yearly meeting of 1764 'recommends to every member of our Society to discourage and suppress the same.' A similar recommendation was issued by the Society in 1851 for the benefit of 'younger Friends' in particular, who would appear to have been eating the forbidden fruit. The Printed Epistle of the yearly meeting of 1724 likewise 'advises against imitating the vain custom of wearing or giving mourning, and all extravagant expenses about the interment of the dead,' and this advice has been repeatedly renewed. A multitude of other minute peculiarities, which it would be tedious to note, distinguish the Friends from their fellow-Christians.

3. *Discipline*.—By the term discipline the Friends understand 'all those arrangements and regulations which are instituted for the civil and religious benefit of a Christian church.' The necessity for such discipline soon began to make itself felt, and the result was the institution of certain meetings or assemblies. These are four in number: the first, the *Preparative* meetings; second, the *Monthly* meetings; third, the *Quarterly* meetings; and, fourth, the *Yearly* meetings. The first are usually composed of the members in any given place, in which there are generally two or more Friends of each sex, whose duty is to act as overseers of the meeting, taking cognizance of births, marriages, burials, removals, &c., the conduct of members, &c., and reporting thereon to the monthly meetings, to whom the executive department of the discipline is chiefly confided. The monthly meetings decide in cases of violation of discipline, and have the power of cutting off or disowning all who by their improper conduct, false doctrines, or other gross errors, bring reproach on the Society, although the accused have the right of appeal to the quarterly meetings, and from these again to the yearly, whose decisions are final. The monthly meetings are also empowered to approve and acknowledge ministers, as well as to appoint 'serious, discreet, and judicious Friends, who are not ministers, tenderly to encourage and help young ministers, and advise others, as they, in the wisdom of God, see occasion.' They also execute a variety of other important duties. The quarterly meetings are composed of several monthly meetings, and exercise a sort of general supervision over the latter, and from whom they receive reports, and to whom they give such advice and decisions as they think right. The yearly meeting consists of select or representative members of the quarterly meetings. Its function is to consider generally the entire condition of the Society in all its aspects. It receives in

writing answers to questions it has previously addressed to the subordinate meetings, deliberates upon them, and legislates accordingly. To it exclusively the legislative power belongs. Though thus constituted somewhat according to Presbyterian order, yet any member of the Society may attend and take part in the proceedings.

Women have also a special sphere of discipline allotted to them: they inspect and relieve the wants of the poor of their own sex, take cognizance of proposals for marriage, deal with female delinquents privately, and under certain restrictions may even do so officially, though in the 'testimony of disownment' they have always the assistance of members of the other sex.

The Society of F., in the multitude of its regulations, has not forgotten the poor; charity in its narrower, as well as in its broader sense, has always been a beautiful feature of its members. The care of the poor was one of the earliest evidences which Christianity afforded to the Gentiles of the superiority and divine character of its principles; and it is honorable to the Society that a similar provision for those united to them in religious fellowship appears to have been one of the earliest occasions of their meetings for discipline. Nevertheless, in accordance with their ruling principle, that all Christian duty should be left for its fulfilment to the spontaneity of Christian love, and not performed under compulsion of any kind, 'the provision for the poor is purely voluntary; yet their liberality is proverbial throughout Britain and America.'

Their number at present amounts, it is believed, to about 120,000, of which more than 90,000 belong to the United States. See Fox's *Journal*; Sewel's *History of the Quakers* (1722); Gurney's *Observations on the Peculiarities of the S. of F.* (1824); Neale's *History of the Puritans*.

FRIES, ELIAS, a distinguished Swedish botanist, was born 15th August 1794, in the district of Femsjö, and studied at Lund, where he became demonstrator in botany in 1828. In 1834 he was translated to the university of Upsala, as professor of practical economics, with which, after the death of Professor Wallenberg, in 1851, the chair of botany was conjoined. F.'s researches embrace the entire field of botany, *phanerogamous* as well as *cryptogamous* plants, and he was the first to introduce into Sweden the morphological theory, the basis of which is to be found in his *Systema Orbis Vegetabilis* (Lund, 1825). His earliest important work was *Observationes Mycologice* (2 vols., Copen. 1815—1818). This was followed by his *Systema Mycologicum* (3 vols. Greifsw. 1821—1829; Supplement, 1830), which was completed in his *Elenchus Fungorum* (2 vols. Greifsw. 1828), and later in his *Novæ Symbolæ Mycologice* (Upsala, 1851). For another department of cryptogamic botany, the lichens, F. did very great service by his *Lichenographia Europæa Reformata* (Lund and Greifsw. 1831). Among his monographs the *Symbolæ ad Historiam Hieraciorum* (Upsala, 1848) deserves especial mention. He wrote a number of works on the *Flora* of Scandinavia, and his *Summa Vegetabilium Scandinaviæ* (Upsala, 1846, et seq.) is especially reckoned one of his best productions. His *Herbarium Normale* (Upsala, 1847), collected at great expense, and with incredible industry, contains dried specimens of all the rarest plants of Scandinavia. F. wrote at various times a multitude of small dissertations on his favorite subjects. In 1851 he was appointed director of the Botanical Museum and Garden attached to the university of Upsala, and in 1853 rector of the university. F., who was a member of the Swedish Academy, retired from work in 1859, and died 8th February 1878.

FRIES, JAKOB, FRIEDRICH, the founder of a philosophic school in Germany, was born at Barby, in Prussian Saxony, 23d August 1773, studied at Leipsic and Jena, and in 1805 went to Heidelberg, as professor of philosophy and mathematics. In 1816 he accepted a call to the chair of speculative philosophy at Jena, but was deprived of his professorship, on account of his participation in certain democratic disturbances of 1819. In 1824, however, he was appointed to the chair of physics and mathematics, which he occupied till his death, 10th August 1843. F.'s writings are very numerous. Some of the more important are his *System der Philosophie als evidente Wissenschaft* (Leip. 1804); *Neue oder anthropologische Kritik der Vernunft* (3 vols. Heidelb. 1807; 2d ed., 1828—1831); *System der Logik* (Heidelb. 1811; 3d ed., 1837); *Handbuch der physischen Anthropologie* (2 vols., Jena, 1820—1821; 2d ed. 1837—1839); *Die Lehren der Seele, des Glaubens, und der Hoffnung* (Heidelb. 1823); and *Geschichte der Philosophie* (2 vols. Halle, 1837—1840). In his philosophy, F. followed the method of Kant, but believing that method incomplete, he sought to supplant it by an analytical nature-doctrine (*analytischen naturlehre*) of the human soul, which he designated philosophic anthropology. His *Glaubenslehre*, or Doctrine of Faith, by which he hoped to repair the ravages which the critical philosophy had made upon the certainty of our knowledge, resembles, in some respects, Jacobi's doctrine of the Intuition of the Pure Reason. De Wette adopted it as the basis of his religious philosophy.

Some of his disciples, Apelt, Schleiden, Schönmilch, Friedrich Francke, and Schmidt, published at Leipzig in 1848—1849, several philosophic papers, entitled *Abhandlungen der Fries'schen Schule*.

FRIE'SLAND, or **VRIESLAND** (ancient *Frisia*), one of the most northern and wealthy provinces of the Netherlands, lies between 52° 40'—53° 30' N. lat. and 5° 30'—6° 20' E. long., and is bounded on the N. by the German Ocean, W. and S.W. by the Zuiderzee. It is sometimes called **WEST FRIESLAND** to distinguish it from **EAST FRIESLAND**, now a part of the Prussian province of Hanover (for which see below). The three divisions of F. are Leenwarden, Heerenveen, and Sneek. Pop. of the province of F. at the census of 1879, 329,877. (In 1875 it was 311,246.) A large import and export trade is carried on, especially with England. The exports to England include potatoes, oats, butter, and cheese.

The land is flat, in some parts below the level of the sea, and is intersected by canals and streams. Lakes and marshes are numerous. The dykes, sluices, and canals are under the care of a special board, and are kept up at the local expense. The inland waters abound with fish. Rich pastures, well suited for the rearing of horses, cattle, sheep, and pigs, cover a third part of the surface. Large quantities of peat are made. The land products are chiefly wheat, rye, barley, oats, buckwheat, beans, peas, potatoes, colza, flax, &c. F. is well supplied with schools and charitable institutions. A sixth part of the population is at school. The capital is Leenwarden (q. v.). Schiermonnikoog and Ameland carry on extensive fishing for cod, haddock, sole, turbot, &c.

East F., in 53° 8'—53° 40' N. lat., and 6° 50'—8° E. long., has an area of 1144 sq. miles, and a pop. amounting, in 1871, to 195,394. It now forms the Hanoverian district of Aurich; chief towns, Emden and Aurich. It is bounded, N. by the German Ocean, W. by the Netherlands, S. by Aremberg, and E. by Oldenburg. Like Netherlands Friesland, it is low and flat, requiring the protection of dikes and sluices. Fishing and agriculture constitute the chief employment of the inhabitants, who are the descendants of the ancient Frisians. This province has frequently changed owners since 1744, when the family of Zirksema, in whose possession it had been for 300 years, became extinct. It was first ceded to Prussia, next incorporated by Napoleon with Holland and France; in 1814 it was restored to Prussia; in 1815 it was ceded to Hanover, along with which it again forms part of Prussia.

FRIEZE, in classical architecture, the central portion of the entablature (q. v.). It is also called (by Vitruvius) the Zophorus (life-bearing) from its being frequently ornamented with sculpture. From the same cause, the term frieze is sometimes applied to any enriched horizontal band.

FRIGATE (probably connected with the Gothic *fargod*, a row-galley, and also with the Latin *aphractus*, an undecked galley),

Frigate—First Class, 50 guns.

formerly, a long narrow vessel propelled by oars and sails, used in the Mediterranean on occasions when speed was requisite. The name then came to be applied to men of war, of a class smaller than line-of-battle ships, and carrying from 20 to 50 guns, which were employed in the great wars of the 18th, and early part of the 19th centuries, as scouts and cruisers. The frigate was usually swift, easily managed, and capable of beating well up to the wind. She became, therefore, the favorite ship in wartime, and bore off a large proportion of the prize-money. Frigates also served to obtain information as to the movements of hostile fleets, and to guide the sailing of their own; but it was unusual for them to join in the line of battle, their exploits ordinarily occurring in engagements with single ships of their own class.

One of Nelson's commonest complaints was, that he had not a larger number of swift frigates to intercept the enemy's cruisers; it having then been notorious that the French built faster and finer craft than those our dockyards could turn out, although it must be added, that most of these rapid frigates had changed their flag before the war closed.

With steam, and the growth of the fleet in later times, frigates were developed more than any other men-of-war, and many of the largest ships in the navy belonged to this class; such as the *Diadem*, *Mersey*, *Orlando*, and the iron-plated *Warrior*, of 6000 tons, three times the burden of any ship of the line in Nelson's fleet. Now, however, these are all ships of the past, incapable of contending with the turreted monsters which carry modern artillery.

FRIGATE BIRD, or **MAN-OF-WAR BIRD**, *Tachypetes aquilus*, or *Fregata aquilus*, a bird of the Pelican family (*Pelecanidae*), the only well-ascertained species of its genus, which is allied to the Cormorants. It is a large bird with black plumage, sometimes

Frigate Bird (*Fregata aquilus*).

measuring ten feet—some say even fourteen feet—from tip to tip of its extended wings. It is a bird of very powerful and rapid flight, and there seems to be good reason for believing that it can remain on wing for days together. It inhabits the intertropical coasts, both of the Atlantic and Pacific Oceans, often flying out far to sea, but returning. Its aerial evolutions are extremely graceful, and it soars to a great elevation. It is said never to dive for its prey, but to seize fishes only when they appear at the surface or above it. Flying fishes constitute no small part of its food.

FRINGE TREE (*Chionanthus*), a genus of plants of the natural order *Oleaceae*, consisting of small trees or large shrubs, natives of America, the West Indies, Ceylon, and New Holland. The Common Fringe tree or **SNOWFLOWER** (*C. Virginica*) is found in the United States from lat. 39° to the Gulf of Mexico. It sometimes attains the height of 20 or 30 feet, but is rarely more than 8 or 10. has opposite oval leaves 6 or 7 inches long, and very numerous snow-white flowers in panicle racemes. The limb of the corolla is divided into four long linear segments, whence the name fringe tree. The fruit is an oval drupe. The tree is frequently cultivated as an ornamental plant.

FRINGES. In optics, those colored bands of diffraction (q. v.) which appear when a beam of light passes the clean edge of a screen, or is transmitted through a narrow slit or hole, are called fringes.

FRINGILLIDÆ, a family of birds of the order *Insectores*, tribe *Conirostres*, having a conical or nearly conical bill, sometimes short and thick, sometimes comparatively slender and elongated sometimes convex above, below, or at the sides, the commissure—line of junction of the mandibles—straight. The neck is short, and neither the legs nor the wings are long. The Fringillidæ are all small birds; they feed chiefly on seeds—to some extent also on insects. The family is an extremely numerous one, and distributed over all parts of the world; represented in Britain by finches, linnets, sparrows, grosbeaks, crossbills, &c., and including also weaver-birds, bob-a-links, cardinal-birds, whydahs, tanagers, &c. Some naturalists extend its limits so as to include in it other groups, as buntings, larks, &c., often regarded as forming distinct families.

FRISCHES HAFF ('Fresh-water Bay'), a large lagoon on the coast of Prussia, south-east of the Gulf of Dantzic. It is rather less than 60 miles in length from north-east to south-west, with a breadth which varies in different parts from 4 to 12 miles, and an area of 318 square miles. It was once entirely walled off from the Baltic by the Frische Nehrung, a narrow spit of land extending for about 40 miles along its northern shore. In 1510, however, the waters of the F. H. broke over the Frische Nehrung, and formed the passage called the 'Gatt,' which unites this shore-lake with the Baltic. The Gatt is only from 10 to 15 feet in

depth. All large vessels load and unload at Pillau, which is situated at the mouth of the Gatt, on the shore of the Gulf of Dantzic. Cargoes are conveyed to and from the ports on the P. H. by means of lighters. The Pregel, Frisching, Passarge, and two arms of the Vistula, fall into this lagoon.

FRISIANS. The Frisians (Lat. *Frisii*), an ancient Teutonic race, dwelt in the north-west of Germany. The origin of the name is lost in antiquity, though traditions, collected and written in *Thet oera Linda Bok*, in the 13th c., say that the Frisians came out of India, and that Frya, the mother of the race, was white as snow. The Frisians are mentioned by Tacitus and Pliny, and occupied the country between the middle arm of the Rhine, which fell into the sea at Katwyk, to the Ems or the Weser. Along with the Batavi, the Bructeri, and the Chauvi, the Frisians became subject to Rome under Drusus, and for a time remained faithful; but, in 28 A.D., these German tribes were driven to hostilities by the oppression of the Romans, and although partially subdued, they again rebelled, 70 A.D., under Claudius Civilis, a Batavian, who made a bold but unsuccessful attempt to overthrow the Roman power in German Gaul. When at a later period the Batavi were absorbed by the Franks, and with them moved southwards, the Frisians took possession of the abandoned districts, and occupied the country from the islands of the Scheldt to the Ems or Weser, so that the Netherlands, except some French and Saxon colonies, were peculiarly Frisian. These formed two branches, the one dwelling west of the Zuiderzee, and the other east of it. The Frisii of the south-west were brought under the Franks by Pepin d'Heristal who defeated them (689), and compelled them to embrace Christianity. The eastern branch (785) was subdued by Charlemagne, who sent Christian teachers to preach the gospel to them, and who (802) defined their right by the *Lex Frisionum*.

Later, the districts now called Friesland were reduced to their present limited boundaries by the formation of the hereditary countships of Holland, Zealand, Gueldres cum Zutphen, and the bishopric of Utrecht cum Yssel. Friesland was independent, and ruled by potentates chosen by the nation and endowed with limited powers, from 802 to 1498. The counts of Holland coveted the sovereignty of Friesland, and internal discord at length gave the Emperor of Germany a pretext for placing Duke Albert of Saxony (1498) as hereditary potentate. His son resigned the right, for a sum of money, to Charles V., who became lord of Friesland as of the rest of the Netherlands. After the revolution in the 16th c., the Frisians had a stadtholder of the house of Nassau-Dietz. Several of these fell in the contest for freedom. Count John William Friso became Prince of Orange on the death of William III. His son, William Karel Hendrik Friso, became stadtholder of the seven united districts. The Frisians are brave, attached to their manners and customs, upright, open-hearted, and intelligent. Their language is closely allied to the old Anglo-Saxon. The favorite poet of the peasantry is Gysbert Japiks. There is a set of laws for the Frisians, composed about 1200, and a complete collection of the laws still extant was published by Richtofen (*Fries Rechtsquellen*, Göttingen, 1840). A Frisian Society of History, Antiquity, and Language, at Leeuwarden, has done much to promote a revival of Frisian literature. Among the historical writers may be mentioned Simon Abbes Gabbema, 1628—1651; Petrus Wierdsma, 1729—1811; Foeke Sjoerds, 1713—1770, &c. Since the 15th c. the Frisian language has gradually given place to the Dutch. It is only used by the peasantry, and not in the schools or churches. Dutch is generally spoken in the towns. Efforts have been made to revive the Frisian by publishing the best specimens of the literature, annuals, &c. Among these are the poetical works of Gysbert Japiks, with a Friesch-Dutch Dictionary of the words, and *Thet oera Linda Bok*, edited and translated by Dr. Ottema, the authenticity of which, like Ossian's poems, has been disputed. The best Frisian dictionaries are the *Friesch-Latin-Nederlandsch Woordenboek* (1874), and Richtofen's *Alfriesisches Wörterbuch* (1840).

FRIT (*Oscinis Frit*, or *Chlorops Frit*), an insect of the same family with the house-fly; an active greenish-black fly of the size of a large flea, which does great injury to barley crops in some parts of the north of Europe. It lays its eggs in the flowers, and its larvæ live on the young grains. Linnaeus affirms that a tenth part of the barley in Sweden and Lapland is usually destroyed by it. It is not known in Britain, but is nearly allied to the insects called corn-fly and wheat-fly.

FRITH, or **FIRTH** (Lat. *fretum*, Gr. *porthmos*; from the same root as Ferry, q. v.), an arm or channel of the sea that is passed or crossed; the opening of a river into the sea.

FRITH, WILLIAM POWELL, R.A., an eminent English artist, the son of an innkeeper at Ripon, Yorkshire, was born in that town in 1819. In 1840, he first exhibited, at the Royal Academy, London, a scene from Shakspeare's *Twelfth Night*, 'Malvolio before the Countess Olivia,' which at once attracted attention, as giving promise of future excellence. In 1841, his painting of the

'Parting Interview of Leicester and his Countess Amy,' from Scott's *Kenilworth*, evinced a marked improvement in his style and manner. Thenceforth he rose rapidly in public estimation, and his subsequent productions amply confirmed the high anticipations that had been formed of his skill and power. Among the paintings exhibited by him in successive years were the following: 'My Wife would bid both stand up to see which was the Tallest,' a scene from the *Ficar of Wakefield*, in 1842; 'English Merry-making a Hundred Years ago,' in 1847; 'An Old Woman Accused of Witchcraft in the Time of James I.,' in 1848; and 'Coming of Age,' in 1849; &c. F. was elected an Associate of the Academy in 1845, and a Royal Academician in 1853. In 1854, his 'Life at the Seaside' was one of the leading features of the Exhibition. 'The Derby Day,' exhibited in 1858, and 'Claude Duval,' in 1860, are two of his most successful pictures. For the 'Railway Station' (1862), he is said to have received 8700 guineas. In 1865 he painted the 'Marriage of the Prince of Wales.' The series called the 'Road to Ruin' was produced in 1878. F. was elected an honorary member of the Imperial Academy of Fine Arts at Vienna in 1869; of the Royal Academy of Belgium in 1871; and of the Royal Academy of Sweden in 1873.

FRITHJOF'S SAGA, which was probably first written down at the end of the 13th or in the beginning of the 14th c., is an ancient Icelandic myth, which records the life and adventures of the hero Frithjof (properly *Fridthjofr*; i.e., 'peace-destroyer') who loved the beautiful Ingeborg, the daughter of a petty king of Norway. After being rejected by the brothers of Ingeborg, and having committed various acts of revenge on his enemies, he comes to the court of the old king Hring, to whom Ingeborg has been married, and is received with kindness. At the death of her husband, Ingeborg is married to her lover, who acquires with her hand the dominions of Hring, over which he rules prosperously to the end of his days. Frithjof is supposed to have lived in the 8th c.; but some writers assign to him a much earlier period. This Saga was included by Björner in his collection *Nordiska Kämpadater* (Stock. 1737); and by Rafn in his *Fornaldar Sögur Norðrlanda* (Copen. 1829). Attention has of late years been more especially drawn to this ancient Saga, which is, in fact, merely one of a number of similar mythical narratives, in consequence of the distinguished Swedish poet, Bishop Tegner, having selected it for the groundwork of a poem (*Frithjof's Saga*), which was published in its complete form in 1825, and at once became the most popular poem that ever appeared in Sweden, and raised its author to the height of his reputation. Tegner follows the Saga so closely, that the merits or demerits of the plan of the story must be ascribed more to the original than to himself; but to foreigners the poem scarcely seems to present the excellences that have been attributed to it by Swedish critics. The diversity of metre employed in the 24 cantos, of which each differs wholly from the others, detracts from the completeness of the whole, and produces an inharmonious effect. The *Frithjof's Saga* of Tegner has been translated into several other languages; among six or seven English translations, we may instance those by R. G. Latham (1838) and G. Stephens (1841).

FRITILLARY (*Fritillaria*), a genus of plants of the natural order *Liliaceæ*, herbaceous, bulbous-rooted, with bell-shaped perianth of six distinct segments, each having a conspicuous honey-pore (nectary) at the base. About twenty species are known, natives of Europe and other temperate regions of the northern hemisphere. All of them have drooping flowers; some of them are beautiful. One species only is a native of Britain, the **COMMON F.** (*F. meleagris*), which is found in meadows and pastures in the east and south of England, flowering in April or May. The stem, about a foot high, bears several linear leaves, and in general only one flower, which is flesh-colored, and marked with many dark spots. Many varieties are in cultivation. —This genus includes the **CROWN IMPERIAL** (*F. imperialis*), a native of Persia and the north of India, a well-known ornament of our gardens.

FRITILLARY, a name given to a number of species of butterfly, some of which are common in Britain, from the resemblance of the coloring of their wings to that of the petals of the common

Crown Imperial (*Fritillaria imperialis*).

fritillary. This resemblance appears only on the upper side of the wings, the under side being often remarkable for metallic brilliancy.

FRIULI (Ger. *Friuli*; anc. *Forum Julii*), the old name of a region lying at the head of the Gulf of Venice, early divided into *Austrian* and *Venetian F.* The former comprises the Austrian districts of Görz and Gradiska and Idria; the latter, the Italian province of Udine. F. is rich in corn and wine; has much metallic wealth and numerous mineral springs. The inhabitants of Venetian F. are mostly *Parlani*, speaking a dialect akin to Italian, mixed with Celtic elements. Austrian F. is peopled mainly by Slavs, with many Italians. F. constituted one of the 36 duchies into which the Lombards divided the north of Italy, and shared the vicissitudes of its neighbor states.

FRIVOLOUS AND VEXATION'S. By 9 Geo. IV. c. 22, s. 15, it was enacted, that if the Select Committee of the House of Commons, appointed to try a petition against an election, should be of opinion that any ground of objection stated against a voter was *frivolous* or *vexatious*, they should find the opposite party entitled to recover the full costs incurred by reason of such objection. Since 1868, jurisdiction in such cases has been transferred from the House of Commons Committee to her Majesty's judges. See **ELECTION.** Vexatious indictments for various crimes are prohibited by 22 and 23 Vict. c. 17. As to frivolous and vexatious actions at law, see 3 and 4 Vict. c. 24, and 4 and 5 Vict. c. 28.

FRÖBEL, or FROEBEL. FRIEDRICH W. A., founder of the Kindergarten (q. v.) system of education, was born at Oberweissbach, 21st April 1782. He followed various occupations ere he discovered where his real strength lay; but in 1805 he taught in a model school at Frankfurt-on-the-Maine with much success, and afterwards he entered Pestalozzi's institution at Yverdon. In the campaign of 1813, he served as a volunteer. In 1817 he established a school at Keilhau, in Thuringia, to carry out his principle of promoting the full and harmonious development of child nature. After fourteen years' labors, he went to Switzerland, where he founded several schools. On his return to Germany, he devoted himself to the education of very young children; and in 1837 he opened at Blankenburg, his celebrated *Kindergarten*, or 'Garden of Children,' which, however, languished for want of funds, and had ultimately to be given up. As F.'s views and his system were confounded with those of a socialist nephew, Karl F., the Prussian government actually prohibited the founding of schools on F.'s principles; and it was naturally not till after his death that the Kindergarten system—found acceptance in Germany. In the later years of his life, F. employed himself in training female teachers. He died at Marienthal, 21st June 1852. F. wrote *Die Menschenerziehung; Pädagogik des Kindergartens; and Mutter- und Koselieder.*—JULIUS, a nephew of F.'s, has distinguished himself as journalist and democratic politician.

FROBENIUS, JOANNES, the learned printer of Basel, was born in 1460. As correctors to the press, he employed such men as Ecolampadius and Erasmus; and between 1491 and 1527, the year of his death, he issued 300 works (including all those of Erasmus), well printed and very free of error.

FROBISHER, SIR MARTIN, a distinguished naval adventurer of the Elizabethan period, the first Englishman who sought to discover a north-west passage to China, was a native of Doncaster, but the year of his birth is unknown. For many years, he in vain labored to impress English merchants with an idea of the importance of a north-west passage; but at length, being patronized by some persons of rank and fortune, he succeeded in raising money enough to fit out two small vessels of 25 tons each, and a pinnacle of ten tons. With these he sailed from Deptford on June 8, 1576, the queen, who was then at Greenwich, bidding them God speed on their venturesome way by 'shaking her hand at them out of the window.' Steering their course north, they, in lat. 61° N., sighted the southern part of Greenland, which F. took to be the Friesland of Zeno, on the 11th July, to the east point of which F. gave the name of 'Queen Elizabeth's Foreland;' and on the 28th, they sighted *Meta Incongnita*. On the 11th August, F. entered the inlet which bears his name, then thought to be one of the entrances from Davis' Strait into Hudson's Bay.

After about a fortnight's exploration of the coasts and islands, F.—having lost, through the treachery of the natives, a boat and five men—returned to England. He brought with him some ore picked up on one of the islands he discovered, in which some gold was found. Visions of immense wealth to be derived from further search in these northern lands floated before the eyes of the speculators of the time, who immediately fitted out another and better appointed expedition, giving the command to Frobisher. He sailed in May 1577, but his discoveries, hampered as he was by the gold-seeking operations, which turned out comparatively trifling, did not extend further than the neighborhood of the strait he had before reached. A third expedition was sent out in the year following; but geographical science appears to have been

but little benefited by it. F. afterwards served under Drake in the West Indies; and for his distinguished bravery in the fight with the Spanish Armada, July 26, 1588, he received the honor of knighthood. He afterwards commanded a squadron sent out to ravage the Spanish coast. He died on November 7, 1594, from the effects of a wound received while leading an attack by sea against Brest.

FROBISHER BAY, an inlet opening westward near the mouth of Davis' Strait into the territory called by Frobisher *Meta Incongnita*, at the southern end of Baffin Land. It is about 200 miles long by above 20 wide, with rugged mountainous shores. It was till Hall's voyage called Frobisher *Strait*, being erroneously regarded as a passage into Hudson's Bay.

FROG (*Rana*), a genus of *Batrachia* having in the adult state four legs and no tail, no gills, four toes on each of the fore-feet, five on each of the hind-feet, the feet more or less webbed; the head flat, the muzzle rounded; the mouth very large, a row of small teeth in the upper jaw, and an interrupted transverse row on the middle of the palate. The young (tadpoles) breathe by means of gills; external gills forming little fringes at the sides of the neck when they are very young, which, however, in a few days disappear; the gills, which remain until the tadpoles un-

Frog:
Successive stages—in the order of the numbers—from the egg almost to the perfect form.

dergo their final metamorphosis into frogs, being very numerous minute crests attached to four cartilaginous arches on each side of the neck in a cavity to which the water enters from the mouth, and from which it is expelled by one or two small orifices. Tadpoles have no legs, and the body tapers into a tail, and thus has a fish-like form, very different from that of the mature F., the tail being furnished with a membranous border like a fin. The mouth of the tadpole is a horny beak, which falls off when it becomes a frog. When this metamorphosis takes place, the hind-legs grow first, and afterwards the fore-legs begin to appear, the tail being gradually absorbed. Tadpoles are capable of living in water only; but the mature F. visits the water only occasionally, although generally capable of remaining long immersed, and always preferring moist places.

In respiration, frogs draw in air through the nostrils, by movements of the muscles of the throat, and expel it by contraction of those of the lower part of the abdomen. The thin smooth skin of frogs is also believed to be subservient to the aëration of the blood. The skeleton is destitute of ribs. The eye is large and very beautiful. The colors are often pleasing, and the general aspect agreeable, in some species very much so, forming a strong contrast to the repulsive appearance presented by toads, notwithstanding the close affinity between them both in structure and habits. The greater proportionate length and strength of the hind-legs enables frogs to leap to a distance wonderful for creatures of their size, instead of crawling as toads do, and their activity and liveliness complete the contrast. The males have on each side of the neck a delicate membrane, which becomes inflated with air when they croak. The power of voice in the females is much inferior. The croaking of numerous frogs in marshy places, or around ponds and ditches, often makes an amusing and curious concert; but the powers of voice possessed by the frogs of Britain are not to be compared with those of the great Bull-frogs (q. v.) of North America; whilst the neighborhood of Rio Janeiro is enlivened as night comes on by the Blacksmith F., which croaks so sonorously that the noise is like the clanging of a hammer on an anvil, the intermingled voices of some other kinds resembling the lowing of cattle at a distance; and in Peru, there is a F., of large dimensions, which has acquired the name of *Trapichero*, or Sugar-miller, because its voice has a grating sound like that produced by a sugar-mill. The confused blending of the voices of different

species of frogs, in these countries, destroying the stillness of night, is one of the things most certain to arrest the attention of the stranger. In colder climates, frogs usually bury themselves in mud, and spend the winter in torpidity. In dry weather, they conceal themselves under shrubs and in tufts of herbage, from which rain quickly causes them to come forth, multitudes often appearing where not one was to be seen before. They feed chiefly on insects, slugs, &c. The heads of tadpoles are adapted to the eating of leaves and other vegetable food, on which Cuvier says they entirely subsist; but the younger Buckland, in his *Curiosities of Natural History* (4th ed., Lond. 1859, pp. 2—4), in an amusing account of the habits of tadpoles, more correctly describes them as showing a great avidity for animal food, crowding round a dead kitten, and nibbling at the toes of little boys who wade in pools where they abound. The spawn of frogs is a gelatinous mass, in which the eggs are contained, and which swells greatly by imbibing moisture. Impregnation takes place after it is deposited, as with the spawn of fishes.

The only species of F. certainly known to be British is that called in France the RED F. (*R. temporaria*), which is abundant in most parts of England and Scotland, but is said not to be truly indigenous in Ireland, and to have been introduced into that island in 1696. Its generally reddish color, varied with black spots and patches, readily distinguishes it from the GREEN F. or EDIBLE F. (*R. esculenta*) of the south of Europe—sometimes said also to have been found in Britain—which is olive green, with yellow stripes along the back, and generally larger than the red species. The south of Europe produces a number of other species, and they are generally more numerous in warmer climates. A remarkable peculiarity is exhibited by some frogs of tropical countries in a hornlike prominence above each eye. These have been separated into a new genus (*Ceratophrys*). The TREE FROGS (q. v.), (*Hyla*), the most beautiful and interesting of all, have the extremities of the toes enlarged into a sort of cushion, secreting a viscid humor. Several other genera have been separated from the Linnean genus *Rana*, but there is a strong family likeness among them all.

The use of frogs for food is generally regarded with disgust in Britain, but it is very common in some of the southern countries of Europe, and they are regarded as particularly delicate. The species chiefly used as food in Europe is the GREEN F. (*Rana esculenta*), already mentioned, which greatly abounds in ponds and slow streams in France, Southern Germany, and Italy. It feeds chiefly on insects, after which it darts with great agility on the banks, and may often be seen swimming with its head above water, or basking in the sunshine. Frogs are there taken for the market by nets, and by a kind of rake. In Vienna, they are kept and fattened in preserves adapted to the purpose. In France, the hind-quarters alone are prepared for the table; in Germany, all the muscular parts. They are dressed in various ways, and with various sauces, of which a great part often consists of wine.—The GRUNTING F. (*R. grunniens*) of the West Indies, a very large species, six or eight inches long, capable of leaping over a five-foot wall, is much used for food, its flesh being very white and delicate, and is often fattened for the table. It shows a considerable capacity for domestication, and readily becomes familiar.—A species of F. (*Pyxicephalus adspersus* of Dr. Smith) is much used as food by the native tribes of South Africa. Dr. Livingstone says the Bechuanas suppose it to fall from thunder-clouds, because after a thunder-shower the pools become alive with frogs, till then hidden in holes. This species is nearly six inches long, and when cooked resembles chicken. See articles AMPHIBIA, BATRACHIA, and *The Common Frog*, St. Geo. Mivart, 1878.

FROG-BIT. See HYDROCHARIDEÆ.

FROG-FISH (*Batrachus*), a genus of Acanthopterygian fishes of the family Lophiidae, to which also the Angler (q. v.) or Fishing Frog belongs. They are remarkable for excessive ugliness. The head is larger than the body; flattened, and spiny; the mouth is very large, with many teeth; the lips are often furnished with filaments; the pectoral fins are supported by a short stalk or wrist. The skin is naked in some species, scaly in others. The species are numerous and widely distributed, but none of them is British. They hide themselves in the sand to surprise their prey.

FROGGED, a term used in regard to uniforms, and applied to stripes or workings of braid or lace, as ornaments, mostly on the breast, on the plain cloth of which a coat is made.

FROISSART, JEAN, a French poet and historian, was born at Valenciennes, in the year 1337. Being destined for the church, he received a liberal education, but soon displayed a passion for poetry and the charms of knightly society. At the age of 20, he began to write a history of the wars of his time, and made several journeys to examine the theater of the events he was about to relate. The composition of this work, which forms the first part of

his *Chronicles*, occupied him about three years (1357—1360). On its completion, he went over to England, where he was received with great favor by Philippa of Hainault, wife of Edward III. In 1362, she appointed him clerk of her chapel and secretary. Two years afterwards, he visited Scotland, where he became the guest of King David Bruce, and also of William Earl of Douglas. Everywhere the gay, poetical, quick-witted, and shrewdly observant Frenchman was welcomed and honored. In 1366, he accompanied the Black Prince to Aquitaine and Bordeaux. He afterwards went with the Duke of Clarence to Italy. F., along with Chaucer and Petrarch, was present at the marriage of this prince, at Milan, with the daughter of Galeazzo Visconti, and directed the festivities given by Amadeus VI., of Savoy, in honor of the duke. On the death of his protectress Philippa, F. gave up all connection with England, and, after many adventures, entered the service of Wenceslaus, Duke of Brabant, as private secretary. The duke was himself a poet, and F. made a collection of his verses, to which he added some of his own, and entitled the whole *Meliador, or the Knight of the Golden Sun*. On the death of Wenceslaus, he entered the service of Guy, Count of Blois, who encouraged him to continue his *Chronicles*. He now took a journey to the court of Gaston Phœbus, Count de Foix, that he might hear from the lips of the knights of Bearn and Gascony an account of their exploits. F. also made several other journeys, to collect information for his *Chronicles*. In 1394 he obtained the canonry and treasurer'ship of the collegiate church of Chinay; in the following year visited England, where he was courteously and generously entertained by King Richard II.; and on his return spent the remainder of his life in completing his great work. He died at Chinay in 1410. F.'s *Chronicles* embrace the events occurring 1326—1400. They are valuable documents for illustrating the character and manners of his age.

The pageantry of feudal times brightens his pages; the din of arms, the shouting of knights, and the marshalling of troops, is ever and anon heard; while 'visions of fair women' rise before us as we read. The gorgeous feasts and spectacles in which F. so much delighted are set forth in copious details; and through F. is no philosopher, his shrewd observations and richly minute descriptions have helped others to philosophize. F.'s *Chronicles* first appeared at Paris about the end of the 15th c., under the title of *Chroniques de France, d'Angleterre, d'Ecosse, d'Espagne de Bretagne, de Gascogne, Flandres et lieux d'alentour*. The best edition is that of Buchon (15 vols., Par. 1824—1826). His poems have likewise been published by Buchon (Par. 1829). The beautiful MS. of the *Chronicles* in the library at Breslau was executed in 1468, and was secured to the town in a separate article, when Breslau capitulated to the French in the year 1806. The *Chronicles* have also been translated into Latin and several modern languages. England has two versions: one executed in 1523—1525 by Bouchier Lord Berners (reprinted in 1812); and the other in 1803—1805 by Thomas Johnes (reprinted by Bohn in 1845). The latter is the more exact; but the former, according to Sir Walter Scott, is the more artless and lively.

FROME, or FROME SELWOOD, a parliamentary and municipal borough, in the east of Somersetshire, on the Frome, a branch of the Avon, 12 miles south-south-east of Bath. The surrounding country is very picturesque, and the town, until modernized early in the present century by the formation of two wide thoroughfares, was a strange old place, with narrow, crooked, and steep streets and lanes, many of which still remain. It manufactures woollens, hats, silk, and cards for dressing woollen cloth. F. has long been famed for its ale. Pop. (1881) 9376. It returns one member to parliament. The once celebrated forest of Selwood was in the vicinity, and part of it remains in its original state.

FROND, in Botany, a term often used to designate the leaves of cryptogamous plants. It was originally introduced as distinctive of organs in which the functions of stem and leaf are combined, and was applied to the leaves of palms, &c. The term *leaf* is now very generally used even as to mosses, ferns, &c., and the term *thallus* is employed as to lichens. In the case of many *Algae*, the term F. is often used to designate the whole plant except its organs of reproduction.

FRONDE, the name given to a political faction in France during the minority of Louis XIV., which was hostile to the court and the prime minister, Mazarin, and caused great domestic troubles from the year 1648 to 1654. The grasping and despotic policy of Mazarin, to whom Anne of Austria, the queen-regent, had abandoned the reins of government, had given offence to all classes. The princes and nobles saw themselves excluded from all high offices in the state, and their place supplied by foreigners; the parliament of Paris was threatened in its political rights, and the people groaned under the burden of taxes and administrative abuses. The parliament commenced a course of de-

terminated opposition, refusing to register the royal edicts, more especially the disgraceful financial measures.

Although the young king, then only nine years old, was obliged by several 'Beds of Justice' (q. v.) to compel the registration of the edicts, and to forbid the opposition of the parliament, the latter did not on that account change its bearing towards the court. Mazarin, therefore, adopted violent measures. On the 26th August 1648, he ordered the president, Potier de Blancmenil, and the councillor, Peter Broussel, to be arrested. The people took up arms, dispersed the Swiss guard, and on the 27th August (*la journée des barricades*), erected barricades in the streets around the Palais Royal. The court now yielded, repealed several taxes, and promised a better administration of justice. This victory gave parliament courage; those members who continued to keep a sharp look-out on the court measures, and were styled by the adherents of Mazarin *frondeurs*—i. e., censurers (literally, 'slingers')—formed the majority. The court now resolved to suppress the movement, in which the populace of the capital had also taken part, by force of arms, and, on the 6th January 1649, removed secretly to St. Germain, leaving Paris to be blockaded by the Prince of Condé with 7000 men. The parliament, whose cause was now publicly espoused by the Prince of Conti, the Dukes of Longueville, Beaufort, Orleans, Bouillon, Elbeuf, Vendôme, Nemours, the Cardinal De Retz, and the Maréchal de la Mothe, called upon the people to resist, and even negotiated with the stadtholder of the Netherlands for an auxiliary corps. In this critical position, the court, on the 11th March, concluded a compact at Ruel, in which both parties missed their object. After the return of the court to Paris in August, a new turn was given to the contest, the princes of the blood disputing the power with Mazarin. This, on the 18th January 1650, led to the sudden arrest of Condé, Longueville, and Conti. This arbitrary proceeding roused the provinces. Marshal Turenne assumed the title of lieutenant-general of the royal army for the liberation of the princes, united himself with the Arch-duke Leopold, and took several fortified towns, but was finally completely defeated by Mazarin's troops at Rhetel, on the 15th December. Mazarin returned in triumph to Paris, but found all parties against him, and his removal was insisted upon so urgently, that he was obliged to release the princes, and flee to the Netherlands. A disgraceful system of intrigue was now substituted for force of arms, which totally changed the position of parties, and converted the contest which had begun for the interests of the people into a court cabal. Turenne was gained over by the queen-regent, De Retz by Cardinal Mazarin, and Condé was obliged to flee for safety into Guienne. Meanwhile, Louis XIV., who had now attained his 14th year, endeavored to induce the Prince of Condé to return; but the latter, mistrusting these overtures, repaired to Bordeaux in 1651, where he had many adherents, whence he commenced a regular war against the court, which might have had dangerous consequences, had not Turenne opposed the prince. On the 2d July 1652, an engagement took place between the two parties in the neighborhood of Paris. Condé was on the eve of being defeated, when the gates of Paris were opened to him by the courage and zeal of his sister, the Duchess of Longueville, and thus a new turn was given to the contest.

Paris itself, weary of these fruitless dissensions, now entered into negotiations with the court, demanding the final removal of Mazarin, who had meanwhile returned. This demand was complied with by Louis XIV., and a general amnesty proclaimed. Condé, who refused to enter into the compact, relying upon an army of 12,000 men placed at his disposal by Charles, Duke of Lorraine, quitted Paris on the 15th October 1652, and repaired to Champagne; and finally finding no one disposed to take up arms in his cause, entered the Spanish service, for which he was declared a traitor. Soon after, Mazarin returned to Paris, and was again intrusted with the reins of government. Thus the royal power came forth victorious from this long contest, which, though it seemed to commence for the popular interests, gradually changed into a miserable party strife among the nobles. Compare Ste-Aulaire's *Histoire de la F.* (1827, 2d ed. 1860); Fitzpatrick's *Great Condé and the F.* (1873).

FRONTINUS, SEX. JULIUS, a Roman author who flourished in the second half of the first century. In 75 A.D. he was sent to Britain as governor of that island, and obtained a great reputation by his conquest of the Silures, and his vigorous maintenance of the imperial authority. He appears to have been twice consul in the course of his life, and to have held several other important offices. He died about 105 A.D. Several works are attributed to F., only two of which are certainly genuine, the *Strategemata*, a treatise on the Art of War, in four books; and the *De Aquæductibus Urbis Romæ*, in two. The best edition of the first is that of Oudendorp (reprinted with emendations in 1779); of the second, that of Dederich (Wesel, 1841). The *De Aquæductibus* is an important contribution to the history of architecture.

FRO'NTISPIECE, the name generally given to an engraved and decorated title-page of a volume, or an engraving placed opposite the title-page. The term is also sometimes used to denote the front or principal face of a building.

FRONTO, M. CORNELIUS, was born at Cirta, in Numidia, and came to Rome in the reign of the Emperor Hadrian, where he soon obtained a high reputation as a teacher of eloquence. Antoninus Pius intrusted to him the education of Marcus Aurelius and Lucius Verus, both of whom always retained the warmest admiration of their preceptor. F. gradually rose to the highest offices of the empire, became very wealthy, and died, it is thought, about 170 A.D. Until recently, nothing was known of F. as an author, except from a few fragments of a grammatical treatise (*De Differentiis Vocabulorum*); but in the year 1814, Angelo Mai discovered in the Ambrosian Library at Milan a palimpsest, which being deciphered, was found to contain a considerable number of F.'s letters with some short essays. These were published by Mai in 1815; and in the following year an edition was published at Berlin by Niebuhr, who wrote a critical preface, and also printed the commentaries of Buttmann and Heindorf. A few years afterwards, Mai found in the library of the Vatican at Rome another palimpsest containing more than 100 of F.'s letters. The result was a new edition of F. by Mai (Rome, 1823), embodying the new discoveries, which was republished at Ceile in Germany (1832). The contents of these letters are on the whole unimportant, although they help to confirm the good opinion which history has formed of the Emperor Marcus Aurelius; and the style is rapid and declamatory.

FRO'SCHDORF (originally, *Crottendorf*), called by the French *Frohsdorf*, is the name of a village in Lower Austria, rather more than thirty miles from Vienna, and not far from the frontiers of Hungary, on the right bank of the river Leitha. It is celebrated for its splendid castle, which in recent times has acquired a kind of political importance, from having been after 1844 the residence of the Duchess of Angoulême and the rendezvous of the elder Bourbon party. After the death of the duchess it came into the possession of the Comte de Chambord (q. v.), who has greatly beautified the interior.

FROSINO'NE (the *Frusino* of the Volscians) is a town of Italy in the former States of the Church, built on the slope of a hill above the junction of the river Cosa with the Saccro, about 48 miles east-south-east of Rome, on the high-road between Rome and Naples. It is the capital of a delegation of the same name, which used to be notorious for brigandage. The only interesting edifices are the palace of the papal delegate and the remains of an ancient amphitheater. The costumes of F. are among the most admired of Italy. Pop. about 8000.

FROST-BITE is caused by cold depressing the vitality of a part or the whole of the body. The frost-bitten part is at first blue and puffy, from the current of blood through it being suspended; then, should the cold be continued, it becomes pallid, and the painful tingling gives place to numbness and insensibility, and finally to actual death or mortification. Although a sudden violent application of cold may cause death of the tissues, by reducing the temperature to a degree incompatible with animal life, the most common cause of the destructive effects of frost-bite is undoubtedly the excessive reaction which occurs on sudden removal of the cold, or the application of heat; this is especially the case with moist cold.

Baron Larrey believed that 'cold was merely the predisposing cause of frost-bite, and mentions that after the battle of Eylau the French soldiers did not experience any painful sensations during the severe cold varying from 10° to 15° below zero of Reaumur's thermometer; but when the temperature rose from 18° to 20°, they felt the first sensations of cold, and applied for succor, complaining of acute pains in their feet, and of numbness, heaviness, and prickings in the extremities. The parts were scarcely swollen, and of an obscure red color. In some cases, a slight redness was perceptible about the roots of the toes, and on the back of the foot; in others, the toes were destitute of motion, sensibility, and warmth, being already black, and, as it were, dried.' Those of the men who indulged in the warmth of the bivouac fires suffered from frost-bite in much larger proportion than their more hardy comrades.

In this country, most cases of frost-bite are very trifling, the most common being Chilblains (q. v.). Occasionally, in severe winters, more severe cases present themselves at the hospitals in the persons of houseless, ill-nourished unfortunates, whose constitutions have in many instances been enfeebled by spirit-drinking.

The treatment of frost-bite consists in coaxing back by degrees the vitality of the part; this is most prudently effected by friction, at first with snow, then with water at ordinary temperature, no warmth being applied for some time. As the coldness subsides, the painful tingling returns, then redness and heat; in a short time the latter will be above the natural standard, and if not moderated, the part will inflame, and perhaps mortify. It is well to

remember that the part need not have been actually frozen for these symptoms to occur. The person with languid circulation who, coming home with cold wet feet, places them before the fire, or in warm water, may be 'frost-bitten' to all intents and purposes.

FROTH-FLY. FROTH-HOPPER. FROG-FLY, or FROG-HOPPER, the common names of those insects of which the young—larvæ and pupæ—are found in a frothy exudation on plants. They form the family *Cercopidæ* of the order Homoptera, and are allied to *Aphides*, and still more nearly to *Cicadas* and Lantern-flies. The larvæ and pupæ differ little in appearance from the perfect insect except that it possesses wings, which are four in number, and large. The frothy exudations in which they live are produced from the juices of the plants on which they are found; and as they are often in great numbers, crops of various kinds are not unfrequently destroyed or much injured by them, the plants being weakened by loss of sap. They have a proboscis adapted for piercing the bark of the plants on which they feed. They have considerable leaping powers. *Aphrophora spumaria* is an extremely common species in Britain. The frothy exudation is sometimes

Frog Hopper (*Aphrophora spumaria*):

a, larva; b, perfect insect, with wing-covers closed; c, perfect insect, in the act of flight; d, the froth on a plant.

Boecydium Cruciatum. Boecydium Globulæ.

called CUCKOO-SPIT, sometimes FROG-SPITTLE, from fancies entertained as to its origin. It is sometimes so abundant, particularly on willow-trees, that persons walking beneath are wetted by its continual dropping. In tropical countries, the *Cercopidæ* are still more plentiful. Some of the tropical insects of this family are remarkable for their extraordinary forms, resulting from peculiar developments of the first segment of the thorax. This is particularly the case in the genus *Boecydium*, of which two species are here figured.

FROUDE. JAMES ANTHONY, an English historian, was born at Totness, in Devonshire, in the year 1818; studied at Oriel College, Oxford, where he took his degree in 1840; and in 1842 was elected a fellow of Exeter College. Having abandoned his original intention of entering the church, he published, in 1847, a volume of stories, entitled *The Shadows of the Clouds*; and two years later, *The Nemesis of Faith*, a work in which the solemnity and sadness of religious scepticism are relieved by a singularly tender and earnest humanity. The book was written with great and even startling power, and not only cost F. his fellowship, but also a situation to which he had just been appointed at Tasmania. F., for the next few years, employed himself in writing for *Fraser's Magazine* and the *Westminster Review*. His *History of England from the fall of Wolsey to the defeat of the Spanish Armada*, appeared from 1856 to 1869. The peculiarity of this work consists in the use it makes of, and the value it places upon, the state documents of the time, the study of which led F. to reverse not a few historical verdicts, especially that upon Henry VIII. The justness of his views on these and other points has been keenly disputed. Four volumes of *Short Studies on Great Subjects* appeared between 1867 and 1882. F. was elected rector of St. Andrews University in 1869, and received the degree of LL.D. For a short time he was editor of *Fraser's Magazine*. *The English in Ireland in the Eighteenth Century* was published in 1874 (new ed. 1881). In 1874, and again in 1875, F. visited our South African Colonies on a mission from the home government; the result of this visit is embodied in his *Two Lectures on South Africa* (1880). As Carlyle's literary executor, F. edited his *Reminiscences* (1881), and Mrs. Carlyle's *Letters* (3 vols. 1882); and by giving to the world the copious personal criticism and family details contained in these works, he suggested to many, doubts as to his editorial discretion. He also gave us in 1882, two vols. of a biography of Carlyle.

FROZEN STRAIT, a passage separating Southampton Island, in the north of Hudson's Bay, from Melville Peninsula. It is

only 15 miles wide, and is almost constantly impervious to navigation.

FRUCTED. Trees when represented as bearing fruit are said heraldically to be fructed.

FRUCTIDOR (Eng. 'fruit-month') was the name given in the republican calendar of France to the period extending from the 18th of August to the 16th of September. The 18th Fructidor of the year 5 (4th September 1797) is celebrated as the day on which a *coup d'état* saved the republic from the machinations of the Royalists.

FRUCTIFICATION (Lat. the producing of fruit), a term frequently employed in cryptogamic botany, sometimes to denote the whole reproductive system, and sometimes the fruit itself.

FRUCTOSE, or FRUIT-SUGAR, known also as **INVERTED SUGAR**, occurs in association with glucose, or (according to the recent investigations of Buignet) with cane-sugar in many ripe acidulous fruits. In its composition, and in most of its properties, it closely resembles glucose, from which, however, it differs (1), in being incapable of crystallization; and (2), in its action on polarized light; while both glucose (or grape-sugar) and cane-sugar exert a right-handed rotation upon a ray of polarized light, this variety of sugar exerts a left-handed rotation; and hence the term *inverted* has been applied to it.

The composition of fructose is represented by the formula $C_6H_{12}O_6$. When boiled with dilute acids, fructose combines with the elements of water, and passes into glucose. A similar passage of this substance into glucose sometimes occurs spontaneously, as is seen in the gradual crystallization of the sugar in dried fruits. It appears to be procurable only from cane-sugar (or sucrose) by the action either of acids or of a peculiar albuminous ferment which exists in the juice of many ripening fruits.

FRUGO'NI. CARLO INNOCENZO, a much admired and versatile Italian poet, was born at Genoa in 1692, and educated for the church. In 1716 he began to teach rhetoric at Brescia, at which time he had already acquired the reputation of being an elegant writer of prose and verse, both in Latin and Italian. In 1719 he taught in Genoa, and subsequently at Bologna. At the court of Parma, through the patronage of the Cardinal Bentivoglio, he was appointed poet laureate, the stated and prescribed compositions of which post were highly uncongenial to his original and discursive muse; nevertheless the Dukes of Parma showed particular favor to the poet, who returned to Genoa on the death of Duke Antonio, and the accession of the Spanish Infante. In 1733, Pope Clement XII. released F. from his spiritual vows, which had at all times been highly distasteful to him. A grand ode, in celebration of the capture of Oran by the Spaniards, and some other poetic addresses to the king and queen of Spain, reinstated the poet in his former post at the Parmese court. He died in 1768. His numerous writings were published at Parma, 1779, and a complete edition at Luca, 1779. A selection from his works appeared at Brescia, 1782.

FRUIT (*fructus*), in the botanical use of the term, in phanerogamous plants, is a mature ovary containing a seed or seeds; and in cryptogamous plants, as pore-case (*sporangium* or *theca*) containing spores. Other parts of the flower, most frequently the calyx, sometimes remain after flowering is over, undergo a further development, become incorporated with the ovary, and form part of the fruit.

The development of the fruit in phanerogamous plants depends upon the fertilization of the ovules, and when this has not taken place, the flow of sap to the ovary usually soon ceases, and it drops off with all the other remains of the flower; although there are exceptional cases of seedless fruits, as seedless oranges, bananas, grapes, barberries, &c., in which, however, it may be supposed that fertilization takes place, and that unknown causes afterwards operate to prevent the development of the seed, and to direct the flow of sap more exclusively to the nourishment of the more succulent parts, which are thus increased and improved. This supposition is rendered more probable by the circumstance that the production of seedless fruits appears to be sometimes a consequence of age and diminished vigor in trees.

The fruit, like the ovary, may be composed of one carpel, or of more than one. But the fruit sometimes differs from the ovary, through the development of some of the parts, and the non-development or obliteration of others; so that an ovary with several cells may be converted into a one-celled fruit; and of several ovules, all but one may become abortive, so as to produce a one-seeded fruit. Thus the three-celled ovary of the oak and of the hazel with two ovules in each cell, becomes, by the non-development of two cells and five ovules, a fruit with one seed; and the two-celled ovary of the ash, and the three-celled ovary of the cocoa-

nut, likewise produce one-celled and one-seeded fruits. The number of cells may also be increased by the formation of false dissepiments. The structure, too, may be rendered more complex by the development of accessory parts, and is usually profoundly modified in ripening, these changes being in direct relation to the dispersal of the seeds. For the various forms of fruits see Balfour's or Henfrey's *Manual of Botany*; and for classification, see Dickson's *Journal of Botany*, October 1871.

All that is external to the proper integuments of the seed in the ripe fruit is called the *pericarp* (Gr. *peri*, around; and *karpós*, fruit); and this, which varies extremely in size and other characters,

Drupe (section of a Peach).

usually consists of three layers, the outermost of which is called the *epicarp* (Gr. *epi*, upon); the middle one, the *mesocarp* (Gr. *mesos*, middle), or sometimes the *sarcocarp* (Gr. *sarx*, flesh); and the innermost, the *endocarp* (Gr. *endon*, within). These parts exhibit great variety, but it is generally the mesocarp which becomes succulent or fleshy, as in the peach, cherry, plum, and other drupes; and in the pear, apple, and other pomes. In drupes, or stone-fruits, the endocarp is the hard shell which immediately covers the seed; in pomes, it is the scaly lining of the seed-bearing cavities in the center; in both drupes and pomes, the epicarp is the outer skin. So in melons, cucumbers, and gourds, the succulent part is the mesocarp, greatly developed, with a thin epicarp and a thinner endocarp. In the orange, however, and all of that family, the epicarp and mesocarp together form the rind, whilst the pulpy cells belong to the endocarp. In berries, as the gooseberry, grape, &c., the pulpy matter does not belong to any of the layers of the pericarp, but is formed from the placentas of the seeds.

When the fruit, as the fully developed ovary, is considered as a modified leaf or leaves, the epicarp is viewed as representing the epidermis of the lower surface, the endocarp the epidermis of the upper surface, and the mesocarp the substance (*parenchyma*) of the leaf. The midrib of the leaf is traced in the *dorsal suture* of the fruit or of each component carpel, and the *ventral suture* is formed by its folding together and the conjunction of its edges. The dorsal and ventral sutures are very obvious in the pods of pease, beans, &c.; and even in fruits formed of several carpels intimately combined, they often become very apparent when the ripened fruit opens to allow the escape of the seeds. The opening or *dehiscence* (Lat. *dehisco*, to open) of fruits takes place in various ways; thus, the fruit sometimes resolves itself into its original carpels by separation through the *dissepiments*, which divide into two plates forming the sides of the valves, and the carpels further open by their sutures; the pericarp sometimes splits at once by the dorsal sutures of the carpels; sometimes it divides transversely, and throws off a lid; sometimes it opens more partially by pores, &c. Many fruits, however, are indehiscent, some of which are fruits having a very hard pericarp, as nuts, and some are fruits having a soft pericarp and much pulp. The decay of the pericarp is in these cases necessary to the liberation of the seeds, unless when this is accomplished by such means as the fruit becoming the food of animals, by which also the seeds of plants are often widely distributed. The decay of the pericarp seems intended, in many cases, to provide the first nourishment for the young plants which spring from the seeds.

A classification of the different kinds of fruits is extremely difficult, although they afford characters of great importance in descriptive and systematic botany. A convenient primary division of fruits is into those which are formed from one flower, and those which are formed by incorporation of the ovaries of many flowers. Fruits formed from one flower, by far the most numerous of these two classes, are divided into *apocarpous* and *syncarpous*, or into *apocarpous*, *aggregate*, and *syncarpous*. Apocarpous fruits are formed of one carpel, and are either dry or succulent, dehiscent or indehiscent, one-seeded or many-seeded. Aggregate fruits, sometimes included among the apocarpous, are formed of several or many free carpels; sometimes dry, sometimes succulent; sometimes arranged on a convex or elevated receptacle; which becomes succulent in the strawberry, and constitutes the edible part of the fruit; sometimes within a concave receptacle covered by the enlarged tube of the calyx, as in the rose. Syncarpous fruits are formed of several carpels, intimately united in their mature state, so as to form a berry, capsule, pome, silique, &c. Syncarpous fruits sometimes so completely resolve themselves into their original carpels, that these may be regarded as becoming separate achenia. Fruits formed by incorporation of the ovaries of many flowers (collective or anthocarpous fruits) are sometimes dry, as the cones of firs; sometimes succulent, as the pine-apple, the mulberry, and the fig. For further notice of dif-

ferent kinds of fruit, we must refer to particular articles in which they are described, as achenium, berry, capsule, drupe, nut, pome, pod, silique, &c., and to articles on the plants which produce them.

A few plants, particularly the *Coniferae* and *Cycadaceae*, produce seeds really naked or destitute of pericarp. Many other seeds were formerly often described as naked, in which the pericarp exists intimately incorporated with the seed, as the seeds of grasses, *Boraginaceae*, *Labiatae*, *Umbelliferae*, &c. Their real nature is often made apparent by some trace of the style.

The production of ripe fruit is exhaustive to the energies of a plant, and plants ordinarily annual may be preserved in life for several years by preventing it. Very young fruit-trees generally fail to bring fruit to perfection, and the first flowers of melons and gourds are often, for a similar reason, abortive; whilst, on the contrary, any circumstance that favors an accumulation of sap in a particular season, tends to render fruit-trees unusually productive in the next, as when the whole blossoms of a year are killed by frost, or when, from the coldness of the previous summer, flower-buds have not been formed in abundance. Whilst the vital energies of a plant are directed mainly towards the increase of its size, flower-buds are sparingly formed or not at all, as is often the case with fruit-trees growing very luxuriantly, and various modes are adopted to cause the production of flower-buds and of fruit by checking this luxuriance of growth, as by root-pruning, by cutting into the stem of wall-trees to a moderate depth, or by taking off portions of the bark of the stem. Grafting (q. v.) is also of use in this respect, as well as for the propagation of improved varieties of fruit-trees, the qualities of which would, in all probability, not be found exactly the same in their offspring by seed.

In a very immature state, fruits are in general green and soft, and decompose carbonic acid gas in the sunlight, absorbing the carbon, and setting free the oxygen, like leaves and other green parts of plants. As they advance towards maturity, some of them become externally dry and hard, and cease to perform by their surface these functions of vegetation; others, as they become more succulent, change their color, and instead of absorbing carbon and liberating oxygen, absorb oxygen from the atmosphere, and exhale carbonic acid.

It would not be easy to enumerate the peculiar substances which are produced in fruits. Different parts of the same fruit are often extremely different from one another, as the milk and the kernel of the cocoa-nut, its hard shell, and its fibrous husk. Seeds are indeed generally very different in all their qualities from the pericarp or the pulp by which they are surrounded, and the integuments of the seed often not less different from the embryo, of all which a ready illustration may be found in the apple or the grape. The most different chemical products of vegetation are sometimes to be found in different parts of the same fruit, giving them the most varied qualities, as wholesome and poisonous; the succulent part of the fruit, from the kernel of which strychnia is obtained, is said to be harmless, and the seeds of plums contain so much hydrocyanic acid, that to eat many of them would be dangerous; the capsule of the poppy yields opium, but its seed contains nothing of the kind, and is bland and nutritious, abounding in a wholesome fixed oil.

The value of fruits to man—which may safely be asserted to exceed that of all other parts of plants—sometimes, as in the corn-plants, chiefly depends on the farinaceous matter of their seeds, containing starch, gluten, &c.; sometimes, as in the banana and bread-fruit, on the starchy matter of the pulpy part; sometimes, as in nuts, on fixed oils; sometimes, as in many succulent fruits, on sugar and various acids, with gum, pectine, &c. Other fruits, or parts of the same fruits, are valuable for the volatile oils which they yield, and for peculiar principles capable of application to medicinal and other uses, or making them capable of being used as condiments, perfumes, &c. Coffee, cocoa, pepper, vanilla, and many other articles of commerce, are obtained from fruits.

Whilst some fruits are of the highest value as articles of food, others are generally regarded rather as articles of luxury; yet the abundance of succulent fruits in tropical climates is a bountiful provision for real wants, contributing much to the health of the inhabitants. The coolness of succulent fruits render them peculiarly grateful amidst the heat of the tropics; their temperature, when newly gathered, being much below that of the surrounding atmosphere.

Cultivated Fruits.—In its popular use, the term fruit sometimes has almost the same signification as in the language of botanical science; sometimes it is employed as almost exclusively designating the edible succulent fruits. We cannot attempt an enumeration of edible fruits; many will be found noticed in other botanical articles; we can only here observe that they belong to many and very different natural orders, both of endogenous and exogenous, but chiefly of exogenous plants. We propose, however, to conclude this article by an enumeration of the principal cultivated

succulent fruits, including those which are important as articles of food or of commerce.

ENDOGENOUS PLANTS.

<i>Musacæ.</i>	Plantain and Banana.
<i>Bromeliacæ.</i>	Pine-apple.
<i>Palmeæ.</i>	Date.

EXOGENOUS PLANTS.

<i>Moracæ.</i>	Fig. Sycamore. Mulberry.
<i>Artocarpacæ.</i>	Bread-fruit.
<i>Lauracæ.</i>	Avocado Pear.
<i>Solanacæ.</i>	Love-apple, or Tomato. Egg-plant.
<i>Sapotacæ.</i>	Mammee Sapota. Sapodilla. Star-apple.
<i>Ebenacæ.</i>	Date Plum. Kaki.
<i>Oleacæ.</i>	Olive [Differs very much in its nature and uses from all the other fruits here enumerated.]
<i>Vacciniacæ.</i>	Cranberry.
<i>Cornacæ.</i>	Cornel.
<i>Myrtacæ.</i>	Rose-apple. Malay Apple. Ugni. Guava. Pomegranate.
<i>Grossulariacæ.</i>	Gooseberry. Red (and White) Currant. Black Currant.
<i>Cactacæ.</i>	Prickly Pear, or Indian Fig.
<i>Cucurbitacæ.</i>	Melon. Water-melon. Cucumber. Pumpkin. Squash. Gourd.
<i>Passifloracæ.</i>	Granadilla.
<i>Papayacæ.</i>	Papaw.
<i>Rosacæ.</i>	Apple. Pear. Quince. Medlar. Loquat. Peach and Nectarine. Apricot. Plum. Cherry. Raspberry. Strawberry.
<i>Leguminosæ.</i>	Tamarind.
<i>Anacardiaceæ.</i>	Cashew-apple. Mango. Hog-plum. Otaheite Apple.
<i>Rhamnaceæ.</i>	Jujube.
<i>Oxalidacæ.</i>	Carambola.
<i>Vitacæ.</i>	Grape.
<i>Sapindacæ.</i>	Akee. Litchi. Longan. Rambutan. Honey Berry.
<i>Malpighiacæ.</i>	Barbadoes Cherry.
<i>Clusiaceæ.</i>	Mammee Apple. Mangosteen.
<i>Aurantiacæ.</i>	Orange. Lemon. Citron. Shaddock. Forbidden Fruit. Lime. Wampee. Marmelos.
<i>Sterculiacæ.</i>	Durion.
<i>Anonacæ.</i>	Custard Apple.

Nuts, and along with them some fruits, which, although not botanically nuts, resemble them in qualities and uses, will be noticed in a separate article.

Chemical Composition of Fruits.—Our principal knowledge of the composition of different kinds of fruit is due to the important investigations of Fresenius, which are published in *Annalen der*

Chemie und Pharmacie for 1857. In that memoir, he gives the results of upwards of fifty analyses of different fruits, including gooseberries, currants, strawberries, raspberries, mulberries, grapes, cherries, plums, apricots, peaches, apples, and pears. We select the following analyses as representing the composition of some of our most important fruits—viz., (1) the gooseberry; (2) the grape; (3) the cherry; (4) the peach; (5) the apple; and (6) the pear. For the purpose of comparison, the free acid which is present, whether it be malic, citric, or tartaric (all of which occur in fruits), is calculated as hydrated malic acid.

Glucose and fruit-sugar or fructose, are described in the article devoted to these subjects. Under the heading 'Soluble Pectine, Gum, &c.' are included coloring matters, fatty or oily matter in a state of suspension, and organic acids in combination with bases. We shall endeavor to explain briefly the nature of the substances designated in these analyses as pectine and pectose. The term *pectine matters* is applied to a very widely distributed class of substances occurring in the vegetable kingdom, and especially abundant in fleshy fruits and in roots, but whose properties and composition require further investigation. The substance termed *pectose*, which is insoluble in water, occurs in plants, which likewise possess a ferment in solution which converts pectose into *pectine*, which is soluble in water, and is the main constituents of apple and other fruit jellies. (According to Fremy, *pectic acid*, which is closely allied to pectine, is formed in fruits that yield jellies: he has assigned formulas to both these substances, but they are not generally accepted.)

The ratio in which the free acid stands to the sugar varies extremely. For a unit of free acid, the sugar is represented by 1.63 in plums, by 3.00 in currants, by 4.37 in strawberries, by 4.93 in gooseberries, by 7.03 in damsons, by 11.16 in apples, by 17.29 in sweet cherries, by 20.18 in grapes, and by 94.60 in pears; the percentage of sugar is least (1.57 per cent.) in peaches, and greatest (14.93 per cent.) in grapes; while the percentage of free acid is least in pears (0.07 per cent.), and greatest in currants (2.04 per cent.).

Fresenius observes, that as all the fruits contain albuminous or proteine matters, they are serviceable as tissue-forming food; but the albuminous matters are present in such small quantity, that these fruits will not serve without other nitrogenous food to keep the body in health. Thus, to obtain an amount of albuminous matter equivalent to the contents of one egg, we must eat more than a pound of cherries, nearly a pound and a half of grapes, two pound of strawberries, more than two pounds and a half of apples or four pounds of pears. They are, however, of more use as respiratory or heat-giving foods. Fresenius calculates that 1 pound of starch (which is equivalent to about 5.5 pounds of potatoes) may be replaced by 5.4 pounds of grapes, 6.7 of cherries or apples, 10.8 of currants, or 12.3 of strawberries. Fruits are, however, taken not so much for their amount of material nourishment as for their vegetable salts (which are of great therapeutic utility), and for their agreeable flavor. In tracing the connection between the flavor and the chemical composition of fruits, Fresenius finds that the former depends (1) on the ratio in which the acid stands to the sugar, gum, pectine, &c. (the last-named substances masking the ratio in which the acid stands to the sugar); (2) on the presence and delicacy of the aroma; (3) on the proportions between the soluble matters, the insoluble matters, and the water; thus, we usually attach the highest value to those fruits which contain the largest amount of soluble, and the smallest amount of insoluble matters—a peach or a green-gage almost melts in the mouth, because these fruits are relatively poor in cellulose and pectose; while, on the other hand, bilberries represent the opposite extreme, and are rich insoluble ingredients; (4) on cultivation, which is found to cause an increase in the quantity of sugar, and a diminution of the amount of free acid and of insoluble matters; (5) and on favorable seasons, which augment the sugar and other soluble constituents.

The different berries contain, as a general rule, a larger proportion of free acid than stone-fruit or apples and pears; and their acidity is the more obvious to the taste from their containing relatively small quantities of gum and pectine. The following remarks on some of our common varieties of fruits are of practical value.

In *gooseberries*, we recognize an agreeable proportion between the sugar and the acid, the ratio being as 6 to 1 in the sweeter

kinds, and 4 to 1 in less sweet varieties of this fruit. The yellow kinds are far richer in soluble ingredients than the red.

In *Currants*, the ratio of the sugar to the acid is only about 3 to 1; they are therefore very acid to the taste, and when eaten require the addition of sugar.

In *strawberries*, it is the aroma that we chiefly prize. The ratio of the sugar to the acid varies with the season and the species from 2 to 1 to 6·7 to 1 (in the pie-apple strawberry).

A similar remark applies to *raspberries*. In wild raspberries, the ratio is as low as 1·8 to 1, while in cultivated kinds it is as high as 3·5 to 1.

Grapes exceed all other fruits in their amount of sugar, which is seldom less than 12, and sometimes reaches 26 per cent. In good kinds, and in favorable seasons, the ratio of the sugar to the acid is as 29 to 1; in inferior kinds, and in ordinary seasons, it is as 16 to 1; when the ratio falls to 10 to 1, the grapes are unripe and acid. In other fruits, this would be a high ratio, and they would be regarded as sweet. The anomaly may be thus explained. In unripe grapes, the skins are very thick, and contain an extremely acid juice, which overcomes the sugar contained in the interior of the berry. The juice of such grapes is found to be far sweeter than the grapes themselves.

From their large amount of sugar, and from the fact that their acidity for the most part depends on the acid tartrate of potash, which is almost entirely precipitated from the wine, grapes are incomparably superior to any other fruits, in the preparation of wines; and in their fermentation, different varieties of ether of a delicate odor are formed, which, in association with volatile oils that are also present, communicate to the more valued wines their special bouquet.

The ratio of the acid to the sugar in the must (the expressed juice before the commencement of fermentation) affords the best evidence of the season. Thus, in the very bad wine-year of 1847, the ratio was 1:12; in the better wine-year of 1854, it was 1:16; while in the good wine-year of 1848 it was 1:24, the same kind of grape being experimented upon in all the cases.

Apricots and *peaches* consist almost entirely of juice, their solid constituents, after the removal of the stone, being only 1 or 2 per cent. These fruits are esteemed both for their juicy and tender flesh, and for their powerful but delicate aroma.

In *apples* and *pears*, we have an increased quantity of cellulose and pectine, and consequently a relative preponderance of the insoluble constituents. The cellulose contributes to the firmness or hardness of these fruits, while it is to the pectine that they owe their property of gelatinizing when boiled. The well-marked differences of taste, &c., presented by different kinds of apples and pears, are due to the very varying relations that occur between the acid, the sugar, and the pectine, to the greater or less abundance of cellulose, and to the varying nature of the aroma. For equal quantities of sugar, pears contain less acid than apples. In the different kinds of dessert apples, the ratio of the sugar to the acid ranges between 12 to 1 and 22 to 1, while in cooking-apples it averages not more than 8 to 1.

The chemical changes which take place in the fruit during the process of ripening are described in the article *PHYSIOLOGY, VEGETABLE*.

Keeping of Fruit.—Many of the finest fruits undergo very speedy decomposition; and on this account, some of those most highly esteemed in the countries which produce them, have never become articles of commerce, and are only to be enjoyed—except in the state of *jam* or *preserves*—during the season of their ripening. Decomposition takes place most rapidly when fruits are exposed to the air, and particularly to stagnant air, when there is any dampness about them, and when they are subjected to considerable or frequent changes of temperature.

Grapes are imported into Britain from the south of Europe, packed in saw-dust. Unripe gooseberries are kept for making tarts in winter, in bottles or jars, filled up with perfectly dry sand, saw-dust, bran, or the like, closely corked and sealed, after a gentle heat has been applied to expel moisture as much as possible, and placed in a moderate and equable temperature, which is sometimes accomplished by burying them to some depth in the earth. A similar method may be employed with many other fruits. Pears, the finest kinds of which are very apt to rot almost immediately after they reach their perfect maturity, may be kept for months in glazed earthen-ware jars very closely covered, and placed in a cool airy situation, out of the reach of frost. The layers of fruit are separated by the substance used for filling up the interstices, and the pears of the same layer are likewise kept apart, that rottenness in one may not infect the rest, which, with every kind of fruit, is very apt to take place. Another method is to keep them in drawers, the temperature being carefully regulated. Large gardens are often provided with a fruit-room, in which shelves and drawers are allotted to the different kinds of fruit. A moderate and equable temperature, dryness, and careful ventilation, are the principal requisites of the fruit room. Fruit

intended for keeping should be carefully gathered, when almost quite ripe, and all bruising avoided. Pears or apples shaken from the tree cannot be expected to keep so well as those gathered by the hand. Of all the succulent fruits produced in Britain, the apple keeps best, and is therefore most generally used. Fruit intended for keeping is sometimes *sweated* before being placed in the jars or shelves; being laid in heaps for a short time—varying according to the kind of fruit, and extending, in the case of winter-apples to a fortnight or more—that some of the juice may exude through the skin; but the propriety of the practice is doubtful. Some kinds of winter pears and apples can scarcely be said to be ripened till after they are placed in the fruit-room; and medlars are not fit for use till they have reached a state of incipient decay.

FRUIT-GARDEN. Some kinds of fruits have been cultivated from the earliest historic ages. To say nothing of the garden of Eden, and the vineyard which Noah planted after the Deluge, we find in the books of Moses evidence that the cultivation of fruits was much practised in Egypt before the time of the exode of the Israelites; and amongst the Babylonians, the Persians, the Chinese, and the inhabitants of India, it can in like manner be traced back to the most remote antiquity. The Greeks and Romans probably derived their knowledge of the art, as well as many of their finest varieties of fruit-trees, from the East; Charlemagne required attention to be paid to it throughout his wide dominions, and contributed much to its extension in regions of Europe previously too rude for its prevalence; and during the middle ages it was most successfully prosecuted by the monks in the gardens of the monasteries.

The grape, the fig, the melon, and the pomegranate, are among the first fruits of which we find any particular notice in history. The cultivation of the apple, the pear, and some others, is also unquestionably of very great antiquity. Interesting particulars concerning the most important kinds of fruit, will be found under their respective heads.

The cultivation of fruits is generally carried on in connection with that of culinary vegetables, flowers, and other objects of the gardener's care; and the fruit-garden is almost necessarily more or less combined with the kitchen-garden, &c. The term fruit-garden is generally used when the ground between fruit-trees is regularly tilled and made to produce other garden crops; the term Orchard (q. v.), when it is laid down in grass, or cultivated for grain and other agricultural crops. The latter method is practicable only with some, and these the more hardy kinds of fruit-trees.

Fruit-trees, in the open air, are cultivated either as wall-trees, espalier-trees, or standards. The walls intended for fruit-trees are either of brick or stone, the former, however, being preferable, and are generally from ten to fourteen feet high. Walls serve not only for protection from winds, but for the radiation of heat, and thus counterbalance in part the disadvantages of cold climates. The training of wall-trees will be noticed in a separate article. See **WALL-TREES**. Espaliers (q. v.) serve in an inferior degree the purposes of walls. Walls are sometimes flued and artificially heated, by which means early ripening is secured, and varieties of fruit are produced which could not otherwise in the same locality be grown in the open air. The production of fruits belonging to warm climates is also effected in the colder parts of the world by means of Hothouses (q. v.), in which the trees are generally trained either as wall-trees or on frames stretched almost horizontally, both methods being commonly adopted in the same hothouse. Standard trees, which receive no other training than mere pruning, or the occasional tying of a principal branch, to guide it in a particular direction, are further distinguished according to the height of their stem before branching, as *full standards*, with stems six or seven feet high, more common in orchards where cattle are sometimes allowed to graze, than in gardens; *half-standards*, with stems three to five feet high; and *dwarf standards*, which, being otherwise also of small dimensions, and often bearing very fine fruit, and in great abundance, are particularly suitable for many situations, and for small gardens. The height of the stem is determined in the nursery, before grafting; but much depends upon the kind of tree; and all the varieties of some kinds may be permanently dwarfed by grafting on particular kinds of stock, as apple-trees by grafting on *paradise* stocks. Other means of still further dwarfing are practised as to trees intended for Forcing (q. v.), and to a remarkable extent by the Chinese in the cultivation of the Dwarfed Trees (q. v.), for which they are famous.

The soil of the fruit-garden requires particular attention. Different kinds of fruit-trees differ, indeed, as to the soils to which they are specially adapted, or in which they will succeed; but a rich and rather open soil is the most generally suitable. This soil must be of the depth of at least two feet, and it is better that it should be three or more; it must extend to a distance of at least eight or twelve feet from the trees, if they are not very dwarf. If

the roots reach a bad subsoil, such as gravel or *till*, canker is almost sure to ensue.

The care bestowed on the preparation of the soil for fruit-trees by the monks of the middle ages has seldom been equalled, and never exceeded in modern times. The whole soil of large gardens appears in some instances to have been artificially prepared; and the descent of the roots to an unfavorable subsoil was prevented by pavements. It is, of course, absolutely requisite that a fruit-garden be thoroughly drained. Manuring is sometimes unavoidable, but is apt, when injudiciously applied, to cause diseases in the trees; and when the soil requires to be enriched, road-scrappings, the scourings of ditches, rotten leaves, &c., are to be preferred. The use of guano and other artificial manures requires great caution. Where full crops of culinary vegetables are taken from the soil around the trees, there is less danger of injury from manures, although the practice, however necessary in many cases, is not the best either for the quality of the vegetables or the fruit.

The fruit-trees cultivated in Britain are almost always grafted or budded on seedling stocks either of the same or a nearly allied species. See GRAFTING. The raising and grafting of these stocks are generally carried on in the Nursery (q. v.). Some kinds of trees are propagated by layers or by suckers, and some by cuttings, the common method of propagating the varieties of gooseberries and currants. In warmer climates, these methods of propagation are more extensively used, and ungrafted seedlings are also more frequently allowed to become trees and to produce fruit. Concerning the transplanting of young fruit-trees, see TRANSPLANTING.—PRUNING will also be noticed in a separate article.—The methods of preserving the blossom from spring frosts being almost exclusively applicable to wall-trees, will be noticed under that head.

Besides fruit-trees, properly so called, some shrubs or bushes are much cultivated in Britain for the fruit which they produce, particularly the gooseberry, the red and white currant, and the black currant. Some of the fruits of tropical countries are in like manner produced by shrubs. The raspberry is only half-shrubby, the strawberry completely herbaceous; and these are the only half-shrubby or herbaceous plants much cultivated in the open air in Britain for their fruit. But in warmer climates, some of the most valuable fruits are produced by herbaceous plants, as the melon, cucumber, pumpkin, and all the kinds of gourds, the pineapple, and, notwithstanding the tree-like size of the plants, the plantain and banana.

FRUIT-PIGEON (*Carpophaga*), a genus of *Columbidae* (q. v.), having the bill considerably depressed at the base, compressed and

Fruit Pigeon (*Carpophaga Oceanica*).

moderately arched at the tip, the membrane in which the nostrils are pierced little prominent or swollen, the forehead low, and the feathers advancing on the soft part of the bill, the wings moderately long, the feet, and particularly the hinder claw, large, and formed for grasping. During the breeding-season, a curious gristly knob grows on the base of the upper mandible of some of the species, and soon after disappears. They are birds of splendid plumage, natives of the forests of India, the Indian Archipelago, the warmer parts of Australia, and the islands of the Pacific Ocean. Their food consists of fruits.

FRUITS, in Law. The fruits of the soil, in their legal aspects, fall under various categories, and follow different destinations according to their nature, and the situation in which they are placed. If not yet separated from the soil which produced them, they are said to be *pendentes*, and as parts of the soil (*partes soli*), pass to the heir on the death of the ancestor, or are carried by a sale to the purchaser. To this, however, there is an exception in the case of industrial fruits (*fructus industriales*), such as growing corn, and all those other fruits which require yearly seed and in-

dustry. These are called in England *emblements*, and 'though still in union with the soil, follow nevertheless, in several particulars, the nature of personal, as distinguished from real estate.' Stephen's *Com.* ii 227. The rule is the same in Scotland, but it is strictly construed, and does not include trees or planting, natural grass, or even fruit not yet plucked from the tree. To this again, however, there is an exception in horticultural subjects, in favor of nursery-trees and plants, not of larger or longer growth than such as are usually dealt in by nurserymen. See FIXTURES. Fruits that are separated from the soil (*fructus percepti*), on the other hand, are the property of the possessor who separated them in good faith; of the tenant or former proprietor in the case of a sale; and of the personal representatives of the deceased in case of death, and not of the heir of his real or heritable estate.

The act 7 and 8 Geo. IV. c. 30, 'for consolidating and amending the laws of England relative to malicious injuries to property,' applies to trees, saplings, shrubs, and underwood; to plants, fruits, and vegetable productions in gardens, orchards, nursery-grounds, hothouses, green-houses, or conservatories; and to various kinds of cultivated roots and plants not growing in a garden, orchard, or nursery-ground. The punishments are proportioned to the injury done, whipping in certain cases being added to the statutory punishments in the case of males, by 16 and 17 Vict. c. 99, and 20 and 21 Vict. c. 3. This statute (7 and 8 Geo. IV. c. 30) is limited to England, but there is an Irish statute in some respects corresponding to it (16 and 17 Vict. c. 38). In Scotland, the trees of an orchard fall under the act for preserving planting (1698 c. 16), and several still earlier enactments; and the breaking of orchard is an offence punishable by the sheriff (Ersk. i. 4, 4). See ORCHARD, PLANTATION. Injuries done to trees or other fruits of the soil are punishable at common law, independently of all statutory provisions, as malicious mischief, both in England and in Scotland.

FRUIT-TRADE. The trade in fruit is divided into two distinct branches—the *fresh* and the *dried* fruits. Fresh fruits, such as those which grow abundantly in England, are sold for London consumption almost entirely at Covent Garden Market; the sales at the Borough and other metropolitan markets being comparatively small.

There are many fruit-gardens within twenty miles of the metropolis which depend almost wholly on London consumption; but since the extensive spread of railway accommodation, fruit can now be brought up from distant parts of England with great facility; and provincial towns and the metropolis can alike be well supplied. Rapid conveyance and prompt sale and delivery are essential conditions to this kind of trade, owing to the tendency of the fruit to spoil by keeping. The higher the quality of the fruit, the more certain is the sale in London. There are in the island of Jersey pear-orchards, the produce of which is contracted for at very high prices by some of the Covent Garden dealers. The orange and lemon trades are managed in rather a peculiar manner; the produce is brought to England in very swift vessels, and is mostly consigned to fruit-merchants in the neighborhood of Lower Thames Street, who sell it to the fruiterers and the street-dealers, as well as to the markets.

Dried fruit comprises raisins, currants, figs, and the like. Grown and dried in foreign countries, chiefly bordering on the Mediterranean, these kinds of fruit mostly arrive in cases and casks; and the dealings connected with them are conducted much in the same way as those with what is called colonial produce, such as grocery.

Of raisins, currants, oranges, and lemons, the quantity and value imported into the United Kingdom in 1880 were as follows:

Raisins, 395,290 cwt.	£728,934
Currants, 820,146 cwt.	£1,072,926
Oranges and Lemons, 3,653,799 bushels.	£1,463,019

We present the numbers for one year, but it was a year of more than average activity in this branch of trade. Of other kinds of fruit, the official tables present the following quantities, in round numbers, for the same year—Almonds, 86,763 cwt.; figs, 85,913 cwt.; plums (French), 13,029 cwt.; prunes, 37,372 cwt.; nuts, unenumerated, to the value of £510,277; raw fruit, unenumerated, 5,133,432 bushels, value £2,239,473; dried fruit, 146,599 bushels, of the value of £106,343; preserved fruit (without sugar), 15,307,601 lbs., of the value of £155,060.

Some years ago, statistical papers in the *Morning Chronicle* gave returns concerning the quantity of fruit sold in Covent Garden and other London markets annually, estimated in the usual way by bushels, cwt., pottles, &c. About the same period, Mr. Braithwaite Poole, goods-manager on the London and North-western Railway, gave tables of the amount, estimated in tons, of the fruit brought to London generally. The sources of information are not very clearly stated in either case; and as the two accounts are inconsistent one with another, they need not be given here.

FRUMENTIUS, St., apostle of Ethiopia and the Abyssinians, born in Phœnicia towards the beginning of the 4th century. At a very early age, he and another youth, named Edesius, accom-

panied their uncle Meropius, a Greek philosopher from Tyre, on a voyage undertaken for mercantile, or, according to others, for scientific purposes. On their return, they landed on the coast of Abyssinia or Ethiopia, to procure fresh water; but the savage inhabitants, under the pretext of their hostility with the Romans, made an onslaught upon them, and murdered Meropius and the whole crew, sparing only the two boys, whom they found sitting under a tree and reading. They were taken as slaves into the service of the king; and made themselves so beloved that Egedesius was soon raised to the office of cupbearer, while the more sagacious F. became the king's private secretary and accountant. After the death of the monarch, F. was appointed instructor to the young Prince Aizanes, and in this capacity he obtained a still greater influence on the administration of the state affairs. He aided the Christian merchants who sought these parts, in founding a church, and gradually paved the way for the formal introduction of the new creed. In 326, he went to Alexandria—Egedesius having returned to Tyre, where he was made presbyter—and convinced Athanasius, who had recently been nominated Bishop of Alexandria, of the necessity of appointing a special ecclesiastical dignitary for Abyssinia, who should carry out vigorously the work of conversion. Athanasius, in full synod, and with its unanimous approbation, consecrated F. himself Bishop of Axum (Aexuma). The new bishop repaired to Abyssinia, and succeeded in proselytizing large numbers. He is also supposed to have translated the Bible into Ethiopian. See ETHIOPIA. On his subsequent theological disputations with Theophilus the Arian—F. himself being in all probability an Athanasian—we cannot enlarge here. F. died about 360, and his day is celebrated by the Latins on the 27th of October, by the Greeks on the 30th of November, and by the Abyssinians on the 18th of December.—Socrates, i. 15; Rufin, *Hist. Eccl.* i. 9; Theodoret, i. 22; Ludolf, *Hist. Eth.* iii. 7, 17, &c.

FRUSTUM, in Geometry, is the part of a solid next the base, left on cutting off the top by a plane parallel to the base. The frustum of a sphere or spheroid, however, is any part of these solids comprised between two circular sections; and the middle frustum of a sphere is that whose ends are equal circles, having the center of the sphere in the middle of it, and equally distant from both ends.

FRY, ELIZABETH, an eminent female philanthropist and preacher of the Society of Friends, third daughter of John Gurney, Esq. of Earham Hall, near Norwich, was born May 21, 1780. Her active and untiring exertions in the cause of suffering humanity, unparalleled in one of her own sex, acquired for her in her lifetime the name of 'the female Howard.' When not more than eighteen years of age, she established a school for eighty poor children in her father's house, with his entire sanction. In 1800, at the age of twenty, she married Joseph Fry, Esq., of Upton, Essex, then engaged in business in London, to whom she had a family of eight children. In the year 1813, the deplorable condition of the female prisoners in Newgate attracted her attention, and she resolved upon visiting them.

Alone and unprotected, she entered the part of the prison where 160 of the most disorderly were immured, and addressed them with a dignity, power, and gentleness which at once fixed their attention. She then read and expounded a portion of Scripture, many of those unhappy beings having on that occasion heard the word of God for the first time. It was not, however, till about Christmas 1816 that she commenced her systematic visits to Newgate, being then particularly induced thereto by the reports of the gentlemen who, in 1815, originated the 'Society for the Improvement of Prison Discipline.' She instituted a school within the prison walls, provided work for the females, and the means of Christian instruction, and established a committee of ladies for the reformation of female prisoners. The almost immediate result was order, sobriety, and neatness, in the place of riot, licentiousness, idleness, and filth, which had previously prevailed. In 1818, her exertions were directed to making provision for the benefit of female convicts sentenced to transportation. For the relief of females in foreign prisons, she made frequent continental journeys. She also interested herself in the abolition of slavery, the advance of education, and the distribution of Bibles and tracts. Her labors for the improvement of British seamen, by furnishing the ships of the Coast Guard and the Royal Navy with libraries of religious and instructive books, received the sanction and assistance of government. To the poor and helpless, her charities were unbounded. As a preacher among her own sect, she was held in high estimation; and she often engaged in gospel missions, not only throughout England, Scotland, and Ireland, but to various countries on the continent. She died at Ramsgate, October 12, 1845, aged sixty-five. Soon after her death, a public meeting was held in London, the lord mayor in the chair, for establishing, as the best monument to her memory, 'The Elizabeth Fry Refuge,' for affording temporary food and shelter to destitute females, on their discharge from metropolitan prisons. Compare *Memoirs of the Life of Elizabeth Fry*, 2 vols. (Lond. 1847), published by her daughters.

FRYING. See FOOD AND DRINK.

FRYXELL, ANDERS, a Swedish historian, was born in 1795 at Hesselkog, in Dalaland; studied at Upsala; took priests orders in 1820; and in 1828, became rector of St. Mary's School, Stockholm. He afterwards became Provost of North Vermland, but resigned this post in 1847. F. first required a reputation by his *Berättelser ur Svenska Historien* (Narratives from Swedish History, vols. i.—xviii., Stockh. 1832—1852). These narratives, strung together on something of the same plan as Sir Walter Scott's *Tales of a Grandfather*, are marked not only by their patriotic sentiment, but by their fresh and natural conception, their richness of biographic detail, their naive and vivacious execution, and soon obtained a wide popularity in Sweden. The first volumes of this truly national work have been repeatedly published, and have been translated into almost all European languages; for example, into English by Schoultz (1841), and German by Homberg (1843).

The part devoted to the history of Gustavus Adolphus has also been translated into German by Homberg (1842—1843), into French by Mlle. N. du Puget (1839), and into Dutch by Radjjs (Utrecht, 1844); and that devoted to the history of Gustavus Vasa into German by Ekendahl (1831). F.'s *Characteristics of the Period from 1592 to 1600 in Sweden* obtained a prize offered by the Swedish Academy. Another work, entitled *Om Aristokrat-fördommet i Svenska Historien* (4 vols. Upsala, 1845—1850), in which he endeavors to clear the Swedish aristocracy from the accusations urged against them by Geijer and others, involved him in a keen controversy with the democratic liberal party in Sweden. F. also addicted himself to poetry and music; and an opera of his, called *Vermland's Flickan* (or 'The Lass of Vermland'), has proved very attractive to his countrymen. F. died at Stockholm, 21st March 1881.

FUAD-MEHMED, Pasha, a Turkish statesman and litterateur, was born at Constantinople in 1814. He was the son of the celebrated poet, Izzet-Effendi-Kitchegizadé, better known under the name of Izzet-Mollah, and nephew of Leila Khatun, one of the very few Turkish poetesses. Having received an education more literary than that of the majority of young men destined for public affairs in Turkey, he began to make himself known as an author, when the exile of his father, who had fallen into disgrace with the Sultan Mahmud, and the confiscation of the paternal property, compelled him to choose a profession. He betook himself to medicine, and studied at Galata-Seraï from 1828 to 1832. In 1834 he was appointed Admiralty physician, and accompanied the grand admiral in his expedition against Tripoli; but on his return to Constantinople, he abruptly forsook medicine, and entered the more unquiet arena of politics. For several years, he employed himself in the study of diplomacy, history, modern languages, the rights of nations, and political economy. In 1840, he became first secretary to the Turkish embassy at London, where his skill and sagacity first made themselves conspicuous. In 1843 he was named second dragoman of the Sublime Porte, and shortly after was chosen to proceed to Spain to felicitate the queen of that country on her accession to the throne. F. was very popular at the court of Madrid. It was almost impossible to believe him to be a Turk. He spoke French marvelously well, made *bon-mots* like Talleyrand, and showed himself as gallant as an Abencerrage. Curiously enough, although a *Mohammedan*, he obtained, while in Spain, among other honors, the Grand Cord of Isabella the Catholic. Here also he composed a poem on the Alhambra, which Turkish critics praise highly for its novel and interesting reflections. On his return to Constantinople, he was appointed to discharge the functions of grand interpreter to the Porte, which brought him into contact with the Duke of Montpensier, who arrived at Constantinople in 1845, and who, on his return to France, invested him with the Cross of Commander of the Legion of Honor.

In 1850 he went on a mission to St. Petersburg, and in 1853 on another to Egypt. On his return from the first of these, he became minister of foreign affairs under the grand viziership of Aali Pasha (August 1852). On the question of the 'Holy Places,' F., by his attitude, and by a brochure very hostile to the pretensions of Russia, entitled *La Vérité sur la Question des Lieux Saints*, gave great dissatisfaction to the czar. In 1854, F. went to Epirus along with Omar Pasha, acting sometimes as a diplomatist and sometimes as a general. In the following year he received the title of Pasha, and was again appointed minister of foreign affairs. From 1861 to 1866 he held the office of Grand Vizier. He died in 1869. To him especially it is said Turkey owes the hatti-sherif of 1856, ordering the consolidation of the external defences of the Porte and the institution of telegraphs and light-houses.

When the Turkish Academy of Science and Belles-Lettres was established in 1851, F. was one of the first members, and in the following year he published a *Turkish Grammar*, which is highly esteemed by native scholars. He was loaded with distinctions by European sovereigns.

FUCA, STRAIT OF, a passage separating Washington Territory in the United States from Vancouver's Island, and connecting the Chambers' Cyclo. Vol. III.—44.

Pacific Ocean with the Gulf of Georgia, has its outer or western entrance in lat. $48^{\circ} 10' N.$, and long. $124^{\circ} W.$ It contains several islands, one of which, San Juan, became, in 1859, the subject of a dispute between Great Britain and the United States; the question being, whether it was to be regarded as an appendage of Washington Territory or British Columbia. The question was submitted in 1872, to the Emperor of Germany as arbiter; and he decided that the line of boundary should be run through the Strait of Haro, west of San Juan, thus awarding that island to the United States.

FUCA'CEÆ, according to Lindley, a natural order of Acotyledonous plants; but more generally regarded by botanists as a sub-order of *Algae*. The species are numerous, about 500 being known, mostly growing in salt water. They are distinguished from the other algae by their organs of reproduction, which consist of spores and antheridia, contained in common chambers or conceptacles, which are united in club-shaped receptacles at the end or margins of the fronds. The antheridia contain phytozoa. The frond is sometimes a stalk expanding into a broad blade, and sometimes exhibits no such expansion, and is either simple or variously branched. Many of the F. are provided with vesicles containing air, by the aid of which they are enabled to float in the water. Some attain a great size—*Macrocystis pyrifera* is said to have fronds of 500 to 1500 feet in length; its stem not being thicker than the finger, and the upper branches as slender as pack-thread. Most of the F. contain iodine in very considerable quantity, and some of them are therefore much used for the manufacture of KELP (q. v.), particularly different species of *Fucus*, or Wrack, and *Laminaria*, or Tangle. On account of the soda which they contain, they are also valuable as a manure. Some of them are eatable, containing large quantities of gelatinous matter, as the DULSE (q. v.) TANGLE (q. v.), and BADDERLOCKS (q. v.) of the British coasts, and certain species of *Sargassum* in other parts of the world. The medicinal uses of some of them seem to depend upon the iodine which they contain, and which it is now considered preferable to exhibit in other forms, after it has been extracted.

FU-CHOW-FOO (Happy City), a city and port of China, and capital of the province of Fuh-keen. It is beautifully situated on the left bank of the Min, 25 miles distant from the mouth of that river, in lat. $26^{\circ} 3' N.$, long. about $119^{\circ} 50' E.$, and was opened to foreign commerce by the treaty of 1842. The walls of the city are about 30 feet in height, and 6 miles in circumference, and have seven gates, the gateways of which are constructed of bricks, resting on a foundation of granite. The bridge of forty or fifty arches over the river Min is 12 feet wide, and about 1200 feet long. A Buddhist monastery on Wu-shi-shan has been converted into the city residence of the British consul. The lacquered ware of F. is of special excellence, and the method of preparing it is known only to one family, by whom the secret is jealously kept. The exports during the season 1881 amounted to 97,455,733 lbs. of tea, of the value of about four and a half millions sterling, of which about two-thirds went to Great Britain. The total imports and exports in 1881 amounted to £4,281,140 (mainly imports). Of the 597 vessels which entered and cleared, 459 were British. The chief imports are lead, cotton, woollen goods, and opium. The duties on foreign trade are greater in amount than those received at any port in China, except Shanghai. The population of the city is about 600,000.

FU'CHSIA, a genus of *Onagraceæ* (calycifloral oxogens), containing a large number of species, natives of South America. They are half-shrubby plants, shrubs, sometimes climbers, and small trees, and have generally pendulous red flowers; of which the calyx is funnel-shaped, 4-cleft, finely colored; the corolla 4-petaled; the fruit is a 4-celled berry; the leaves are opposite; the flower-stalks 1-flowered, springing from the axils of the leaves, or sometimes forming racemes at the top of the branches. Some of the species, as *F. coccinea*, *F. gracilis*, *F. globosa*, *F. fulgens*, *F. macrostemon*, *F. longiflora*, are much cultivated in gardens and greenhouses for the beauty of their flowers. Most of the species are too delicate for the climate, at

Fuchsia.

least of the northern parts of Britain; but some of them, although

killed to the ground every winter by frost, spring again from the root, and flower beautifully in autumn. A little protection around the root is of great use in preserving them in vigor. All of them are propagated with extreme facility by cuttings, which has no doubt contributed to their present abundance, even in the gardens and windows of the poor.

No flowering shrubs of recent introduction into Britain have become nearly so popular as those of this genus; and new varieties and hybrids have been produced in vast numbers, of which those with white flowers are particularly prized. The berries of a number of the species are eaten in South America, and preserved with sugar; and they are occasionally used in both these ways in Britain, although in Scotland the fruit even of the most hardy ripens only in favorable situations, for the most part on the west coast. Where the climate admits of it, a F. hedge is extremely ornamental. The wood of some species is employed in their native regions for dyeing black. The genus is named in honor of Leonhard Fuchs, one of the fathers of modern botany, born in Swabia in 1501, died at Tübingen, where he was a professor, in 1565.

FUCHS'S SOLUBLE GLASS is a peculiar silicate, which is prepared by melting together 8 parts of carbonate of soda, or 19 parts of carbonate of potash, with 15 of pure quartz sand, and 1 part of charcoal, which is added to facilitate the decomposition of the alkaline carbonate. A black glass is thus obtained, which is not soluble in cold water, but dissolves in about six times its weight of boiling water. Fuchs commenced his experiments on this subject in 1825, and continued and varied them for many years. The above is, however, we believe the most approved formula. The practical uses of the soluble glass to which he especially directed his attention were two—viz. (1), as a varnish, which, applied in the fluid form to stone surfaces, would harden into a glass, and prevent the ordinary effects of atmospheric influences; and (2) as a means of fixing fresco-colors by the process known as stereochromy. See FRESCO. Professor Kuhlmann of Lille in 1857 published his method of producing a stone-protecting silicate; and used it successfully for preventing the decay of walls and houses built of inferior stone. He also employed soluble glass in print-works and tapestry factories for fixing colors on cotton and on paper. It has also been utilized in washing wool, 40 parts of water being mixed with 1 of soluble glass at a heat of about $130^{\circ} F.$ Mr. Ransome of Ipswich has not only employed concentrated solutions of silicate of potash, or of soda, as a cement for consolidating silicious sand into a very hard, durable, artificial sandstone, capable, before it is fired, of being moulded into any desired form, but has likewise produced a vitreous varnish, consisting of silicate of potash, after which he applies a coating of a solution of chloride of calcium: a silicate of lime is thus formed, which is stated to be very successful in protecting the surface of stone from external influence. Wood that has been painted with these varieties of soluble glass is rendered nearly if not quite fire-proof.

FUCI'NO, LAKE OF, or LAGO DI CELANO (ancient *Fucinus Lacus*), a lake of Italy, in the province of Abruzzo Ultra II., remarkable as the only one of any extent found in the Central Apennines. It is 10 miles long by 7 broad; and is situated at an elevation of 2176 feet above the sea-level. It is subject to sudden risings; and in ancient times, by order of the Emperor Claudius, a magnificent subterranean channel more than three miles in length, to carry off the surplus waters, was cut partly through the solid rock of Monte Salviano, rising 1000 feet above. This tunnel became obstructed in the middle ages, and long remained so, notwithstanding many attempts to clear it. In recent times the surrounding country has been often submerged. In 1855, operations were commenced for the restoration of the Claudian aqueduct, and on the 9th of August 1862 the work was completed. Down till 1871, about £20,000,000 were expended upon the drainage of this lake.

FUCUS. See FUCACEÆ and WRACK.

FUEL. This term is generally applied to combustibles used for the production of heat; also, less frequently, to combustibles such as oil, Paraffine Oil (q. v.), used for lighting. Under articles COAL, COKE, &c., will be found details of the physical properties and chemical composition of the various fuels; the following observations bear chiefly on their economical application as sources of motive power.

The two elementary bodies to which we owe the heating powers of all our fuels, natural and artificial, are carbon and hydrogen. Coke, wood charcoal, peat charcoal, and anthracite, contain little or none of the latter element, and may be regarded as purely carbonaceous fuels. But wood, peat, and most varieties of coal, contain hydrogen as well as carbon; and in their combustion, these two substances combine to produce volatile and combustible hydro-carbons, which are volatilized previous to being consumed, while a purely carbonaceous fuel evolves no volatile matter until combustion has been effected.

These hydrocarbons are numerous and varied in composition (see CARBOHYDROGENS); but when combustion is perfect, the amount of heat produced by any hydrocarbon is exactly what would have been produced had the hydrogen and carbon been burned separately. It will be of advantage, therefore, to study these two elementary combustibles in succession, in order to estimate subsequently the combined effect where they come together in the same fuel.

The heating power of a combustible, or the amount of heat generated by it, is usually expressed in degrees Fahrenheit on so many pounds' weight of water. But in estimating the temperature, or intensity of heat produced, we have to keep in view that different substances have different capacities for heat—that of water being generally assumed as unity. The number expressing this capacity is called the specific heat of the substance. Water 1000, carbonic acid 221, imply that while 1000 units of heat are required to elevate the temperature of water any given number of degrees, only 221 units are required to elevate the same temperature an equal weight of carbonic acid.

CARBON AS FUEL.—1. *Amount of air required for combustion.*—Burned in air, carbon combines with the oxygen to form carbonic acid (CO_2), mingled with nitrogen, the other atmospheric element. The chemical change may be thus represented, atomically:

Products of Combustion.			
Carbon,	6.0	Carbonic acid,	25.0
Air (69.6) { Oxygen,	16.0		
{ Nitrogen,	53.6		53.6
	75.6		75.6

Or, assuming carbon as unity:

Carbon,	1.000	Carbonic acid,	3.667
Air (11.6) { Oxygen,	2.667		
{ Nitrogen,	8.933		8.933
	12.600		12.600

Carbon, therefore, requires about twelve times its own weight of air for perfect combustion.

2. *Amount of Heat produced.*—Andrews found that 1 lb. of carbon produced heat equal to 1°F. in 14,220 lbs. of water. Other observations agree very closely. This may be otherwise stated thus: 1 lb. carbon will raise from freezing to boiling point (32° to $212^\circ = 180^\circ$) $\frac{14220}{180} = 79$ lbs. water; from mean tem-

perature to boiling-point (60° to $212^\circ = 152^\circ$) $\frac{14220}{152} = 93.5$ lbs. water; will boil off in steam from mean temperature (60° to $212^\circ = 152^\circ$, add latent heat in steam. $965^\circ = 1117^\circ$), $\frac{14220}{1117} = 12.73$ lbs. water; and will boil off in steam from boiling-point (latent heat in steam, 965°) $\frac{14220}{965} = 14.74$ lbs.

3. *Utmost Temperature or Intensity of Heat from Carbon.*—Here we suppose the combustion effected in a space enclosed by non-conducting material, so that all the heat produced by 1 lb. carbon is retained by the products of its combustion. Caloric sufficient to raise 14,220 lbs. water 1°F. is thus compressed, as it were, into 12.6 lbs. of carbonic acid and nitrogen. To determine the temperature thus produced, we require to know the specific heat of this gaseous compound, that of water being 1.

3.667 lbs. carbonic acid.	Specific heat,	.2210
8.933 " nitrogen.	" "	.2754
12.600 " products of combustion.	Mean sp. "	.2596

14,220° on water at 1.000 specific heat, will give 54.776° on these products per pound-weight. Distributed over 12.6 lbs., this heat will raise the temperature to $\frac{54776}{12.6} = 4347^\circ \text{F.}$, which is therefore the utmost intensity of heat attainable in burning carbon, supposing no loss by absorption or radiation.

4. *Effect of Excess of Air.*—Excess of air has been proved to have no effect on the quantity of heat produced where combustion is perfect; but the intensity of temperature is diminished. Suppose two equivalents of air admitted; we then have as the products of combustion—

3.667 lbs. carbonic acid.	Specific heat,	.2210
8.933 " nitrogen.	" "	.2754
11.600 " air in excess.	" "	.2669
24.200 " products.	Mean sp. "	.2631

14,220° on water = $54,045^\circ$ on this new mixture of gases. But

the heat is now diffused over 24.2 lbs. matter instead of 12.6 lbs., $\frac{54048}{24.2} = 2234^\circ \text{F.}$: the utmost temperature produced by carbon burned in two equivalents of air.

The utmost temperatures attainable, with various proportions of air, are given below, and also the appearance which the interior of the furnace would exhibit. Flame at these temperatures will present the same differences in color.

Weight.		Ratio of Fuel to Air	Highest Possible Temperature.	Appearance of a Body exposed to such Temperature.
Carbon.	Air.			
lbs.	lbs.			
1.	11.6	1 to 1	4357°	Intensely brilliant.
1.	17.4	1 " $1\frac{1}{2}$	2941	Dazzling white.
1.	23.2	1 " 2	2233	Bright ignition.
1.	29.0	1 " $2\frac{1}{2}$	1797	Full cherry red.
1.	34.8	1 " 3	1503	Commencing cherry red.
1.	58.	1 " 5	908	Incipient red.
1.	69.6	1 " 6	758	Black.

5. *Effect of Deficiency of Air.*—If, before reaching the upper layers of carbon or cinder, the air has parted with all its oxygen to form carbonic acid with the production of heat, then the carbonic acid combines with part of the remaining carbon to form Carbonic Oxide, CO (q. v.), but without producing heat. The loss may amount, therefore, to one-half of the fuel: some have stated it as high as three-fourths. If this oxide, when it gets above the fuel, meet with air before cooling, it burns with a pale blue flame, restoring part of the lost heat; but to what extent has not yet been determined.

6. *Effect of Water Present.*—Passing into vapor, water absorbs both sensible and latent heat, and thus diminishes the temperature. Heating power is also lost, as products of combustion are generally passed into the atmosphere at a high temperature.

HYDROGEN AS FUEL.—1. *Air required.*—Hydrogen combines with the oxygen of the air to form vapor of water, mingled with nitrogen:

Products of Combustion.			
Hydrogen,	1.	Vapor of water,	9.
Air (34.8) { Oxygen,	8.		
{ Nitrogen,	26.8		26.8
	35.8		35.8

1 lb. hydrogen therefore requires 34.8 lbs. air, while 1 lb. carbon requires only 11.6 lbs.

2. *Amount of Heat Produced.*—The amount of heat produced from hydrogen is much greater than that from carbon; the caloric from 1 lb. heating 60,840 lbs. water 1°F. Part of this is, however, latent in the water-vapor, and must be deducted in calculating intensity of heat, and also heating effect under all ordinary circumstances. This deduction amounts to 9 lbs. water $\times 965^\circ$ latent = 8685° , leaving 52,155° as the effective heating power of 1 lb. hydrogen.

3. *Utmost Temperature and Intensity of Heat.*—This is less than in the case of carbon, from the high specific heat and greater quantity of the products. We have—

Vapor of water.	9. lbs.	Specific heat,	.8470
Nitrogen.	26.8 "	" "	.2754
	35.8 "	Mean sp. "	.4191

52,155° on water will be $124,445^\circ$ on these products; and $\frac{124445}{35.8}$

lbs. = 3476° , is the utmost possible temperature.

4. *Effect of Excess of Air.*—As in the case of carbon, the intensity of heat is diminished, as under:

Weight.		Ratio of Fuel to Air.	Highest Possible Temperature.
Hydrogen.	Air.		
lbs.	lbs.		
1.	34.8	1 to 1	3476°
1.	69.6	1 " 2	2187
1.	104.4	1 " 3	1591
1.	139.2	1 " 4	1250

5. *Effect of Deficiency of Air.*—No new product is the result of deficiency of air, as in combustion of carbon; the hydrogen simply escapes unconsumed.

6. *Effect of water-vapor present* is diminution of intensity and ultimate loss of heat in application, as in the case of carbon.

Temperature of Ignition of Carbon and Hydrogen.—These substances must be themselves heated before they can burn. Hydrogen begins to burn at or below 300° , while carbon requires a red-

heat (800° to 1000° F.), and even at that temperature burns very slowly. Consequently, where they are combined, as in common coal, the temperature present is often sufficiently high to ignite and consume the hydrogen, while the carbon remains unchanged as cinder, or passes away as smoke, unconsumed in either case.

All that has been said above, of carbon, as to air required, heating power or value, utmost temperature, temperature of ignition, effect of water present, and of excess or deficiency of air, applies, without modification, to one class of fuels—the purely carbonaceous, including anthracite, coke from coal, charcoal from wood and peat, and the cinder of any description of fuel. The incombustible ash must be allowed for in calculating heating power or value; and also the volatile bodies—nitrogen, sulphur, &c.—the latter of which frequently renders the fuel unsuitable for many purposes in the arts and manufactures.

Peat, wood, and coal, with the exception of anthracite, contain hydrogen to an extent rarely exceeding 5 per cent. We have seen that, compared with carbon, hydrogen requires three times as much air, and generates nearly four times as much heat, but produces 20 per cent. less intensity of heat, and ignites at a much lower temperature; and the combustion of wood, coal, &c., is in these respects modified according to the proportion of hydrogen present in them.

The following table shows the composition of British coal, as determined by Playfair and De la Beche. Columns 8 to 12 are added to illustrate the process of combustion.

When coal is heated in a retort, it yields volatile Hydrocarbons (q. v.), amounting to 20 to 32 per cent. of its weight (see column 11). The hydrogen has robbed the fuel of six times its own weight of carbon. When fresh fuel is added to live coal in a furnace, the same result ensues; so that in using coal, 50 to 67 per cent. of carbon burn on the grate, and 20 to 32 per cent. carbon and hydrogen have to be burned in the open space above the fuel, or escape unconsumed.

The elements of a hydrocarbon are consumed, not simultaneously, but in succession. First, the carbon is separated from the hydrogen in light floating particles, subsequently seen as soot or smoke (if not consumed); then the hydrogen burns, and communicates heat to the carbon particles, which then appear as flame. The color of the flame indicates the temperature present; and if the temperature is sufficiently high, the carbon of which the flame is composed burns also, producing a further increase of heat. If not, the flame, as it moves onward, cools, becoming red, dull red, and finally black and smoky, passing away as such. For complete combustion of common coal, we therefore require not only air in sufficient quantity, but also intensity of heat above the fuel. We require a low temperature to separate the carbon from the hydrogen; a higher temperature to consume the hydrogen; and a still higher to consume the carbon of the flame. In closed furnaces, such as those of steam-boilers, while the current of air supplied continues pretty uniform in quantity, the volatile bodies are evolved almost immediately after fueling; and would require, for the moment, perhaps four times the quantity of air which is passing through. The volatile fuel is, in consequence of the want of air, carried off partly unconsumed; and the temperature in such furnaces is frequently too low for the ignition of carbon, as may be seen from the color of the flame; the cold boiler having abstracted the heat before the flame has been subjected to its influence. We refer to the article SMOKE, CONSUMPTION OF, for an account of the plans which have been adopted to secure perfect combustion, and thus prevent smoke.

From the principles involved, we should expect most success where the fuel is supplied by mechanical arrangements as regularly and uniformly as the air, and where, in addition, the body of the furnace is protected or removed so far from boiler-surface and other cooling agents as is necessary to maintain a temperature within it sufficient for the thorough ignition of the flame. In house-fires, where the heat is lost if not radiated forward into the room, the cinders should be drawn to the front, and the fresh fuel laid into the vacant space behind. The gases rise between the two

and being highly heated, form a sheet of flame above and behind the red-hot fuel in front. If, as is commonly done, we throw the fresh fuel on the top of the live coal, we interrupt the process of radiation, and the gaseous part of the fuel is thrown off rapidly into the cool atmosphere above the grate, and does not take fire until a considerable period has elapsed. To our ordinary fire utensils, we might with advantage add one of a rake shape, suited for drawing forward the fuel.

For dimensions of furnaces, &c., see STEAM-ENGINE.

Economy of fuel will be best secured, first, by accomplishing perfect combustion both of the fixed and volatile parts of the fuel; and secondly, by regulating the amount of air, as any excess of this has to be passed on to the chimney at the same high temperature as the true products of combustion.

The abundance or scarcity of fuel has a great effect on the general interests of a country and the comfort of its inhabitants. The wealth and prosperity of Britain must be attributed in no small degree to the abundance of coal in those districts both of England and Scotland in which ironstone is most abundant, and in which, therefore, the coal is required as fuel for smelting it. But even for the most ordinary uses of domestic economy, the scarcity of fuel in some parts of the world, causes much hardship to their inhabitants, whilst its abundance in others is one of their greatest natural advantages. Coal, wood, and peat are the three kinds of fuel principally used; coal being indeed the vegetation of former ages—or rather of former geological periods—the product of their

sunshine and their showers, treasured up for the present; peat, a recent formation. Coal may be said in general to be of about twice the value of wood as fuel, weight for weight, in its heating power. In those parts of the world in which coal is not found, or to which it cannot be easily—or as yet profitably—conveyed, the preservation of forests is of great importance; and trees are not unfrequently planted, as in some parts of Europe, in hedge-rows and otherwise, chiefly in order to provide a supply of fuel. For the same reason, pollarding is resorted to, the branches being used as fuel, and the trunk left to produce new branches. Only some kinds of trees are adapted to this mode of treatment. In some regions, as on some of the steppes of Asia and other treeless plains, the dried dung of herbivorous animals is much used as fuel. In cases of less extreme necessity, all kinds of vegetable refuse are used. Thus, in many parts of the continent of Europe, things are carefully gathered up for fuel which in any part of Britain would most probably be burned on the field, to get them out of the way. But it is not easy to compute the benefit derived by many parts even of Britain, particularly the inland parts, from the recent great increase of the facilities of communication and of the trade in coal.

FUENTÉ A'LAMO, a town of Spain, in the province of Murcia, 18 miles south from Murcia, at the northern base of a range of hills, and at a short distance from the canal of Murcia. Pop. (1877) 7901.

FUENTE DE OVEJUNA (The Sheep-well), a small walled town of Spain, in the province of Cordova, and 44 miles north-west of the town of that name, is situated on the crest and sides of a conical hill, between two of the upper branches of the Guadiala. At the foot of the hill, and on its western side, are the wells from which this town has derived its name. It has manufactures of finens, woollens, and leather. Coal-seams occur in the vicinity. Pop. about 5500.

FUENTES DE ONORO (The Fountains of Honor), a small village of Salamanca, Spain, on the Portuguese frontier, 14 miles west of Ciudad Rodrigo, is well-known as the scene of one of the important battles of the Peninsula War, between the English under Wellington, and the French under Massena. Wellington, who had resolved to abide battle, drew up his forces between the Coa and the Agueda, his line extending north and south for about seven miles, and his right wing stretching two miles south of F. de Onoro. On the 3d May 1811, this village was fiercely attacked by a strong body of French troops, who forced the

English from the streets, and were not dislodged until the English, reinforced by three regiments, drove them by a terrific charge from their position, with a loss in all of 300 men. On the 5th, the battle proper commenced. The French, much stronger than their enemies both in cavalry and infantry, assailed Wellington's right with overwhelming numbers, and although prodigies of valor were performed by the English—as in the case of Ramsey's brigade of horse artillery, which cut its way through a solid body of cavalry—their right wing was turned, and their position lost. Never during the war were the English forces more perilously situated. Meanwhile, at F. de O., on which Wellington's left wing now rested, a fierce battle was being fought. The three English regiments who had been left in occupation made a desperate resistance against assailing multitudes. The fight lasted here till evening, reinforcements having been brought up on both sides; and the night closed upon the English holding the crags above the town, and the retiring regiments of the French. The loss of the allies amounted to 1500, while that of the French was stated at the time to be nearly 5000, and was certainly greater than that of the allies. Neither army could claim a decided advantage in this battle; but its result was, that on the 10th, the French were forced across the Portuguese frontier; and thus ended the French invasion of Portugal.

FUERO, a Spanish word derived from Lat. *forum*, signifies strictly, the seat of justice, jurisdiction. In this last sense, it was transferred to collections of laws, and specially to the civic rights granted by the kings to individual cities, the most famous of which were the fuero of Leon and that of Naxera. As these city charters contained for the most part special liberties, concessions, and privileges, the word fuero became current chiefly in this sense, and was particularly so applied to designate the body of privileges and liberties that made up the constitution of Navarre, and of the three Basque provinces of Biscaya, Alava, and Guipuzcoa. These are the fueros the maintenance of which gave rise to wars in the Basque provinces in 1833. The fueros of other provinces and cities of Spain have long been extinct.

These Basque fueros were grounded on the old laws of the Visigoths, and grew up in the period between the irruption of the Moors into the Spanish peninsula and the consolidation of the Spanish monarchy under the House of Hapsburg. The same was the case in the half-Basque province of Navarre, which formed an independent kingdom under its own sovereigns. The fueros were thus the product of the ancient Gothic laws—those fertile sources of modern rights—and the new circumstances in which they were placed. They resulted by degrees, here as elsewhere, in a struggle between the people and the princes; and their development forms an interesting chapter in the history of modern constitutionalism. They were at first only privileges and statutory rights granted to single places, and from these were extended to others. By the introduction of the representative element of the Cortes, and extension over whole provinces, they were then transformed, in virtue of the general law of custom, into constitutional rights of these provinces; and were in time collected and formally embodied and sanctioned as such. It was in this way that the fueros of Navarre, which had been growing into consistency for centuries previously, were, in 1236, during the contests between King Theobald and his Cortes, collected and recorded, and remain yet under the title of *Cartulario del Rey Tibaldo*. Ferdinand the Catholic, who united Navarre with the crown of Castile, maintained the fueros, adapting them to the new relation to Castile. Their leading provisions were these: The Cortes, chosen for three years, and consisting of the three estates of clergy, nobles, and commons, are to meet yearly; and without their consent, no law can be passed, or anything of importance undertaken. The government consists of the viceory, who presides in the Cortes and Great Council of Navarre (a body similar to the old French parliaments); and the Contaduria, before which all accounts of revenue and expenditure must be laid. There is no custom-house or toll but at the frontier, and except the trifling grant of 176,000 reals, nothing flows into the royal treasury. All these fueros the king had to bind himself by a royal oath to maintain.

In the lordship (Señoría) of Biscaya, the fueros grew up in the contests of the inhabitants with their counts. They were first collected into a code by Count Juan in 1371, which, after the final union of Biscaya with Castile, was recast (1526), completed, and confirmed by King Charles I. (the German emperor Charles V.). According to this charter of rights, every new 'Lord'—for only so do the Biscayans style the king of Spain as their prince—fourteen years old, must come into the country within a year, and take the oath to uphold the fueros in certain places appointed for that purpose. The government consists of a corregidor, appointed by the 'Lord,' and two deputies; these, aided by six regidores, and forming the regimiento, conduct the administration. But the supreme power resides in the General Assembly (Junta General), which meets yearly under the tree at Guernica,

and regulates all the affairs of the lordship, and appoints the deputies and regidores. Justice is administered, in the first instance, by the lieutenants (Tenientes) of the corregidor; in the second, by the corregidor and deputies; and in the third, by the royal court at Valladolid. Other privileges were, that every Biscayan of pure blood was counted noble; that except the post-office there was to be no royal governing board in the province; that Biscayans were not bound to serve in the Spanish army.

The fueros of Alava and Guipuzcoa were of analogous origin and character, but differing in details. Abolished by Espartero, these fueros were restored by Queen Isabella in 1844. In 1876 a law abolishing the Basque fueros was adopted, and in 1877 a decree was passed, assimilating the administration of the Basque provinces to that of Spain.

FUERTÉ DE ANDALGA'LA, sometimes more briefly called ANDALGALA, a town of the Argentine Confederation, in the province of Catamarca, 72 miles north by west from Catamarca, in a mountainous district. Pop. 5500.

FUERTE, or VILLA DEL FUERTE, a town of Mexico, in the province of Sinaloa, 75 miles north by west from Sinaloa, on the Rio del Fuerte, which flows into the Gulf of California. It is a place of some commercial importance. Pop. 8000.

FUGÆ. See MEDITATIO FUGÆ.

FUGA'RO, the name of a well-known stop of the flute kind in continental organs of 4-foot pitch, and sometimes of 8-foot pitch, of a small scale, made of wood or tin; in tone it is as piercing as the *gamba*, but much clearer.

FUGGER, one of the most remarkable families in Germany, which, rising by industry and commerce, has founded numerous lines of counts, and even princes. The ancestor of the family was John F., master-weaver in Graben, near Augsburg. His eldest son, John F., acquired by marriage, in 1370, the freedom of Augsburg, and began to carry on a trade in linen along with weaving. By a second marriage, in 1382, with the daughter of a councillor, he had two sons and four daughters. This John F. was one of the council of twelve (Ger. *Die Zwölfer*, 'the twelves') in the weaver-guild, and an assessor of the famous *Fehngericht* (q. v.) or secret tribunal of Westphalia. He died in 1409, and left what was a large fortune for the time—3000 guildens or florins.

His eldest son, Andrew F., made such good use of his share of the inheritance that he got the name of 'the Rich Fugger.' By marriage, he founded a noble line, which, however, died out in 1585. John's second son, Jacob F., who died in 1469, was superior and 'twelver' of the weaver-guild, and a man held in high esteem by his fellow-citizens; he was the first of the Fuggers that had a house in Augsburg, and he already carried on an extensive commerce.

Of his seven sons, three, Ulrich, George, and Jacob II., by means of industry, ability, and integrity, extended their business to an extraordinary degree, and laid the foundation for the palmy days of the family. They married into the noblest houses, and were raised by the Emperor Maximilian to the rank of nobles. The emperor mortgaged to them, for 70,000 gold guildens, the country of Kirchberg and the lordship of Weissenhorn, and received from them afterwards, through the mediation of Pope Julius II., 170,000 ducats, to assist in carrying on the war against Venice. Ulrich F., born 1441, died 1510, devoted himself specially to the commerce that he opened up with Austria, and there was almost no object that did not enter into his speculations; even the master-pieces of Albert Dürer went through his hands to Italy. Jacob F., born 1459, died 1525, engaged in mining; he farmed the mines in Tyrol, and accumulated immense wealth; he lent to the Archduke of Austria 150,000 guildens, and built the magnificent castle of Fuggeran, in Tyrol. Thus the wealth of the Fuggers went on increasing. Their wares went to all lands, and scarce a road or sea but bore their wagons or ships.

But it was under Charles V. that the House attained its greatest splendor. Jacob having died childless, and the family of Ulrich being also extinct, the fortunes and splendor of the House rested on the sons of George F., who died in 1506. At his death he left three sons, one of whom, Marcus, entered the church; the two younger, Raimund and Antony, carried on the business, and became the founders of the two chief and still flourishing lines of the House of Fugger. The two brothers were zealous Catholics, and with their wealth supported Eck in his opposition to Luther. During the diet held by Charles V. at Augsburg, in 1530, the emperor lived in Antony F.'s splendid house in the Wine Market. On this occasion, he raised both brothers to the rank of counts, and invested them with the still mortgaged properties of Kirchberg and Weissenhorn; and a letter under the imperial seal conferred on them the rights of princes. For the support they afforded him in his expedition against Algiers in 1535, they received the right of coining money. Antony F., at his death, left six millions gold crowns in ready money, besides jewels and possessions in all parts of Europe and in both Indies. It is of him that the Emperor

Charles is said to have remarked while being shown the royal treasury in Paris: 'There is a linen-weaver in Augsburg that could pay all that out of his own purse.'

The Emperor Ferdinand II. raised the splendor of the House of F. still higher while confirming the imperial letter of Charles, by conferring great additional privileges on the two oldest of the family, Counts John and Jerome. The Fuggers continued still as nobles to carry on their commerce, and further increased their immense wealth. They attained the highest posts in the empire, and several princely houses prided themselves on their alliance with the House of Fugger. They possessed the most extensive libraries and collections of objects of art, maintained painters and musicians, and liberally encouraged art and science. Their houses and gardens were master-pieces of the architecture and taste of the times. There is thus nothing incredible in the story that Antony F., on one occasion when Charles V. was his visitor, lighted a fire of cinnamon wood with the emperor's bond for money lent him.

While thus indulging in splendor, they were not less bent on doing good. Ulrich, George, and Jacob, the sons of the beneficent Jacob, bought houses in one of the suburbs of Augsburg, pulled them down, and built 108 smaller houses, which they let to poor citizens at a low rent. This was the origin of the 'Fuggerei,' which still remains under the same name, with its own walls and gates. Many other benevolent institutions were set on foot by Antony F. and his sons. It is questionable if we are to rank among their benefactions their calling the Jesuits to Augsburg, and giving them buildings and revenues for a college, church, and school. The race is still continued in the two principal lines of Raimund and Antony, besides collateral branches. The domains are chiefly in Bavaria. A collection of portraits of the most important members of this great house, executed by Domin. Custos of Antwerp, appeared at Augsburg (1593 et seq.). This collection (increased to 127, with genealogies written in Latin) was republished by the brothers Kilian (Augsburg 1618); and in 1754, a new edition of the work, still further improved,

and containing 139 portraits, was published at Ulm, under the title *Pinacotheca Fuggerorum*.

FUGUE, in Music, is the name of a composition wherein the parts do not all begin at once, but follow or pursue one another at certain distances; thence the name, *Fuga*, a flight or chase, each part successively taking up the subject or melody. Any of the parts may begin the fugue, but the others follow according to fixed rules. The subject is generally a few bars of melody, which is given out in the principal key by the part which begins. The next part which enters repeats the same melody, but a fifth higher or a fourth lower, and is called the answer. The third part follows with the subject again in the principal key, but an octave higher or lower than the first part, and is answered by the fourth part in the same manner as the second part answers the first. After the subject is completed, the melody which follows it, so as to form a continuation of the part, is called the counterpoint, in the construction of which, facilities for ingenious double counterpoints of various kinds are afforded. When the subject and answer have been introduced in all the parts, the first section of the fugue is said to be completed; an intermediate harmony of a few bars then follows, sometimes in its form like part of the subject, and with a modulation into a nearly related key. The subject and answer are again brought forward, but following in a different order from the first section; while at the same time all the parts are continued, and in some of them the original counterpoint appears either simply or inverted, the subject and answer forming the predominating idea throughout the whole composition, and towards the end appearing in a variety of forms, intervals, and modifications. When the subject does not extend in compass beyond the half of an octave, the answer is invariably made in the other half; and to avoid modulation out of the key, the progression of a fifth is answered by a fourth.

A fugue consisting of one subject with a counterpoint throughout, is called a strict fugue, as in the following example by J. Sebastian Bach, in which the first progression of a fifth is answered by a fourth:

When a second subject is introduced in the middle of the composition, and afterwards worked up with the first subject, it is then called a fugue on two subjects, as in the following from Graun's *Tod Jesu*:

A double fugue begins at once with two subjects in different parts, both of which are strictly treated throughout as in the following from Mozart's *Requiem*:

2d Subject.

Christe ele-is-on, &c.

Ky-ri-e ele-is-on e-le-is-on

A free fugue is that in which the subject and counterpoint are not strictly treated throughout, but mixed up with intermediate harmonies and ideas not connected with the subject, while the rules of the fugue are not rigidly adhered to.

The fugue has always been, and will continue to be, esteemed by every sound musician, not from its being the most difficult style of composition, but from its not being subject to caprice and fashion. The fugues of Bach, Handel, and other composers possess the same interest for the present time as they have done for generations past. Although the fugue is held by many to be a mere mechanical study, which can be composed or written purely by rule and calculation, still, it undoubtedly holds out to a composer of genius a wide field for great and beautiful effects, as well as peculiar artistic combinations. The best works on the fugue are by Marpurg, Albrechtsberger, Kirnberger, and the late Professor S. W. Dehn of Berlin.

FUGITATION. A sentence of fugitation in Scotland corresponds to outlawry in a criminal process in England, and is pronounced where a person fails to appear to answer to a criminal prosecution against him. Amongst other consequences, it entails the escheat of his whole movable property to the crown. See **ESCHEAT**.

FUGITIVE SLAVE LAW. Slaves being regarded as property, things and not persons, as the Roman law puts it, the existence in every state in which slavery exists of a law recognizing the right of the master to reclaim his property follows as a logical consequence. Accordingly, the constitution of the United States of America having recognized slavery, or 'service,' as it was gently termed, by American writers, necessarily used to contain a number of enactments for its enforcement. By art. 4, s. 2 of that document, it was declared that persons held to service or labor in one state, under the laws thereof, and escaping into another, should be delivered up, on claim of the party to whom such service or labor might be due. In furtherance of this provision, the laws of New York provided for the arrest of such fugitives, on *habeas corpus*, founded on due proof, and for a certificate in favor of the right of the claimant, and delivery of the fugitive to him, to be removed. This obsolete law, as narrated in the latest edition of Kent, seems to have been to the following purport: The act of 1793, providing for the reclamation of fugitives from justice and from service, had, so far as relates to the latter, been amended, and to a considerable extent superseded, by the act of September 18, 1850. The judicial duties imposed by the latter act were to be performed by the United States commissioners, who might have the power of arresting or imprisoning for offences against the United States, by the judges of the circuit and district courts of the United States, and of the superior courts of territories, and by such special commissioners as the respective courts might appoint. It was the duty of all United States marshals to obey and execute all warrants and process of such judges and commissioners; and after the arrest of any fugitives, such officers were liable for an escape with or without their assent. When any fugitive escaped into another state or territory, the owner, or his duly authorized agent, might pursue and personally arrest said fugitive, or might demand a warrant and arrest from the officer having due authority. The fugitive was then to be taken before a commissioner or judge, whose duty it was to hear and determine the complaint in a summary manner. Should he have been satisfied of the validity of the claim and the identity of the slave, it was his duty to deliver to the claimant a certificate of the proceeding had, with authority to remove the fugitive to the place from which he fled. The testimony of the fugitive was not admissible. Any assistance rendered to a fugitive to enable him to escape from the claimant, or any obstruction offered to his arrest, was penal, and also subjected the party to damages at the suit of the owner. All citizens of the United States were required, when called upon, to render the officers personal assistance in the performance of their duties. These provisions applied to all the states previously to the war, whether slavery was recognized by their special laws or not; the principle being, that 'the constitu-

tion and laws of the United States secure the right to reclaim fugitive slaves against state legislation.'

In some of the slave-holding states it was held, that if a slave from such a state went lawfully into a non slave-holding state, and acquired a domicile there with his master, or was emancipated there, he became emancipated, and ceased to be a slave on his return; but if he were carried there for a temporary purpose, and returned, his state of slavery was resumed. These provisions did not apply to the fugitive slave (Kent, *ut sup.* ii. p. 297).

FUGLEMAN, (properly, *Fülgelman*, from the German *flügel*, a wing), an intelligent soldier posted in front of a line of men at drill, to give the time and an example of the motions in the manual and platoon exercises. He originally stood in front of the right wing, and hence the name.

FU-HU, or FU-HU-SHE, the first of the five emperors of China that flourished in the mythological period. He instructed the people in the art of rearing cattle, and invented the *pa-kua*, or eight combinations of four strokes, to express the changes of nature. His chief invention, however, was that of letters, by drawing up the two linear tables called Ho-too and Lo-shoo, which he copied from the back of a dragon rising from the deep. According to another account, knotted cords, 20 inches long, were used for writing, till Tsang-ke, the minister of F., conceived the idea of characters from seeing the footprints of birds on the sands. F. instituted marriage, invented the musical instrument called *kin*, and taught the art of fishing. It is clear that he personifies a condition of society. He had a head with projections like the horns of an ox, and the body of a dragon.—*San-tsze-king*, l. 21, 22; Kang-keen-e-che-luh, i. p. 6; Gutzlaff, *Sketch of Chinese History*, i. p. 119.

FU-HU-KEEN, or FU-KIAN (Happy Established, or The Consummation of Happiness), one of the eastern maritime provinces of China. It lies to the south of Che-keang, between the parallels of 23° 35' and 28° 47', and is backed by the great southern range of mountains that separates South-eastern China from the inland provinces. F. belongs to the hilly portion of China proper.

It is a black-tea district, and produces barley, wheat, rice, tobacco, yams, and other Chinese vegetables. The principal fruits are the orange, li-chee, olive, plum, pomello (a fruit of the subacid order, somewhat like an orange), plantain, and mulberry. On its coast are situated the ports of Fu-chow (q. v.) and Amoy, or Hia-mum (the gate or harbor of Hia), opened by the treaty of Nankin, 29th August 1842. See **CHINA**. The island of Formosa and the Pang-hoo group are included in this province. Area, 53,480 square miles; pop. 14,800,000.

FÜHNEN (Dan., *Fyen*), the largest of the Danish islands after Seeland, is bounded on the W. by the Little Belt, which separates it from Jutland and Slesvig; on the N. by the Odensee Fjord; on the E. by the Great Belt; and on the S. by the Little Belt, and by the small island of Langeland, which is incorporated with it in one circle, or *stift*, of the kingdom. The area of this stift is 1302 square miles; the population (1870) was 236,311. The coast is generally rugged, and much indented with bays or fjords; but the interior is flat, except towards the south and west, where there is a range of hills rising to about 500 feet. The land, which is well watered by several small streams, is fruitful and well cultivated, producing abundant crops of cereals. Barley, oats, buckwheat, rye, flax, and hemp are grown in larger quantities than are required for home consumption. Honey is also largely exported. The F. horses are in great request, and large numbers of these animals, and of a fine breed of horned cattle, are annually sent out of the island. The province of F. is divided into the two bailiwicks of Odensee and Svendborg. The principal towns are Odensee (q. v.), Svendborg (q. v.), and Nyborg—pop. (1870) 4812—a fortified town on the east coast, and the most direct port of communication with Seeland, and memorable as having been the seat of the annual Danehof, or meeting of the States, instituted in 1354 by Valdemar IV., and for the victory gained in 1659 by the Danes and their allies over the Swedes.

FULAHS [properly, *Fülbe* (sing. *Pullo*), called also *Féllani* (sing. *Baféllanelli*), *Felláta*, and *Fulán*], the name of a widely spread negro people in Upper Súdán, regarding whose origin there is much diversity of opinion. M. Eichwaldt (see *Journal de la Société Ethnologique*, 1841, vol. i. p. 2, et seq.) has endeavored to connect them with the Malays in the far East, but, according to Dr. Barth, 'none of his arguments are of any consequence.' Yet Dr. Barth himself is of opinion that 'their origin is to be sought for in the direction of the East; but this,' he adds, 'refers to an

age which for us is enveloped in impenetrable darkness.' The F. first emerge into the light of history about the beginning of the 14th c., when, as we learn from Ahmed Bárá's *History of Súdán*, two members of the tribe went on a religious mission from Melle, on the borders of Senegambia, to the king of Bórnu. The importance of this incident lies in the fact, that it shows that in the dawn of their history—as has invariably been the case in later times—the course of the tribe was from west to east, and also, that at the early period referred to, they were distinguished for that religious learning which still characterizes them. After the 14th c., successive swarms of F. appear to have left the kingdom of Melle, or the mountainous regions of Fuládu, and to have spread themselves over the greater portion of Súdán, absorbing and incorporating with themselves different and quite distinct national elements, which have given to their community a rather varying and undecided character. Hence originate the conflicting accounts of travelers, some of whom speak of F. as differing little from the negroes; others, as having their features and skulls cast in the European mould; while Bowen describes those of Yoruba as being some black, some almost white, and many of a mulatto color, varying from dark to very bright.

Many other tribes, which have not been quite absorbed by the F., are yet so far blended with them, that they have lost their native idiom altogether, and speak the language of the predominant race, which is termed the Fulfúlde. The F. are not all under one ruler; they are a *race*, not a *nation*; and have founded many kingdoms, such as those of Sókoto, Gando, Timbo, &c. The endless tribes belonging to their stock are generally divided into four groups or families, the Jel, the B'aa, the Só, and the Beri. Most of them became converted to Mohammedanism about the middle of the 18th c., and in 1802, under the Imám Othman, commenced a religious war on the surrounding pagans, which terminated prosperously in the establishment of the great Fulah empire of Sókoto. Othman died in a sort of fanatical ecstasy or madness in 1818. The F. are industrious and inclined to trade; they work iron and silver, manufacture with great neatness articles in wood and leather, and weave various durable fabrics. They are by far the most intelligent of the inhabitants of Súdán, and have, besides mosques, schools in almost all their towns.

FULCRUM, in Mechanics, is the prop or fixed point on which a lever moves. See LEVER.

FULDA, a town of Germany, in the Prussian province of Hesse-Nassau, 54 miles south of Cassel, is pleasantly situated on a rising-ground on the right bank of the Fulda, a considerable stream, which, rising from the western base of the Rhöngebirge, in Bavaria, flows northward through Hesse-Cassel, and unites with the Werra on the Hanoverian border, after a course of 110 miles. It is a pretty town, surrounded by old walls, and has a market-place, two squares, and eight suburbs. One of the chief buildings is the cathedral, the fourth church that has been built on this site. It is a handsome modern structure, and covers the shrine in which the body of St. Bonifacius was deposited after his murder by the Frisians in 754. The other notable structures are the palace, formerly the residence of the prince-bishops of F.; the church of St. Michael, founded in 822; a gymnasium, schools of art and manufactures, and a public library. F. has acquired a reputation for its linen manufactures; it has also extensive establishments for the manufacture of vinegar and beer; with dye-works, tanneries, and weaving. Pop. (1880) 11,507, mostly Roman Catholics. The district of which F. is the capital, forms part of what was formerly the grand-duchy of Fulda. This territory was incorporated with the grand-duchy of Frankfurt by Napoleon in 1810, and ceded to Prussia in 1815, but immediately afterwards was made over to Hesse-Cassel (q. v.).

FULGORA. See LANTERN-FLY.

FULGURITES (Lat., *fulgur*, lightning), tubes formed of vitrified sand, which are found in sand-banks, and in soils consisting chiefly of silicious sand, and are attributed to the action of lightning melting and vitrifying the sand. They were first discovered in 1711 by the pastor Herman, at Massel, in Silesia, and have since been found in many places; but their origin was first pointed out by Dr. Hentzen in 1805. They are from a quarter of an inch to two inches and a half in diameter, their internal surface of a perfectly glassy substance, hard enough to scratch glass, and to give fire with steel. They are usually, but not always, placed vertically in the sand, become narrower downwards, and sometimes divide and sub-divide into branches.—The effects of lightning seem to be exhibited also in some places on rocks by vitrification and the production of a sort of enamel, sometimes assuming the form of beads.

FULHAM, formerly a village, but now a suburb of London, in the south of Middlesex, on the left bank of the Thames, six miles south-west of St. Paul's. Here is the palace of the bishops of London.

FULICA. See COOT.

FULIGULA. See POCHARD.

FULLER, ANDREW, an eminent Baptist minister, and theological and controversial writer, the son of a small farmer, was born at Wicken, Cambridgeshire, February 6, 1754. He received the rudiments of his education at the free school of Soham, and in his youth was principally engaged in agricultural labors. In his 17th year, he became a member of a Baptist church at Soham, and in 1775 he was chosen pastor of a congregation at that place. His small stipend of £21 per annum he endeavored to increase by keeping, first a small shop, and then a school. In 1792, he removed to Kettering, Northamptonshire, to take the pastorate of a congregation there. On the formation, in 1792, of the Baptist Missionary Society by Dr. Carey, himself, and eleven other ministers, he was appointed its secretary, and the whole of his future life was devoted to the administration of its affairs. In 1794 he published a controversial treatise, entitled *The Calvinistic and Socinian Systems, examined and compared as to their Moral Tendency* (Lond. 8vo.). This work was attacked by Dr. Toulmin and Mr. Kentish, and F. replied in a pamphlet, entitled *Socinianism Indefensible* (Lond. 1797, 8vo.). His other principal publications are *The Gospel its own Witness* (Clipstone, 1797), and *Expository Discourse on the Book of Genesis* (2 vols. 8vo, Lond. 1806). He was also the author of a variety of single sermons and pamphlets. The sense, sagacity, and thoroughly practical knowledge of mankind which these writings display, have won for F. the title of 'the Franklin of Theology.' He died May 7, 1815. Three collected editions of his works have been published, besides American reprints; the first in 10 vols. 8vo, the second in 5, and the third in 1 royal 8vo. A volume of his treatises was republished in Bohn's Standard Library, with a Memoir by his son. F.'s *Memoir of the Rev. Samuel Pearce of Birmingham* is much esteemed as a religious biography.

FULLER, SARAH MARGARET, MARCHIONESS OSSOLI, one of the most remarkable women of the time, was born at Cambridge-Port, Massachusetts, May 23, 1810. Her father, Timothy Fuller, was an advocate, and gave his daughter an excellent education, and nurtured her with great care. At eight years of age she wrote Latin verses; and philosophy, history, and aesthetics were her favorite studies. At ten she read Tasso and Ariosto in the original, and subsequently made herself familiar with the German writers, Tieck, Schelling, and Novalis. After her father's death she assisted her family by private teaching, and in 1839 she founded a society for ladies, where she herself delivered lectures. From 1839 to 1844, she edited *The Dial*, to which she contributed many admirable articles. In compliance with an invitation she received from Horace Greeley, the editor of the *Tribune*, she proceeded to New York in 1844, and contributed to that journal a series of articles on literature and art, which have since appeared in a collected form under the title of *Papers on Literature and Art* (London, 1846). In 1850, she published *Women in the Nineteenth Century*, in which she very ably discusses the nature and destiny of women, and claims for the sex rights which have been long denied it. In 1846, she proceeded to England, where she made the acquaintance of Carlyle, for whom she had long entertained a high esteem. At Paris she gained the friendship of Madame Dudevant, better known by her pseudonym of *Georges Sand*. Proceeding next to Rome, she there came in contact with the Marquis d'Ossoli, to whom she was afterwards married in December 1847. She took an active share in the political questions that agitated those times. In 1849, during the siege of Rome, she took the charge of an hospital; and viewed with feelings of pain the downfall of the new and ephemeral Roman Republic. In 1850, she set out on her return journey to America, accompanied by her husband and newly-born infant; but just as they came within sight of New York, on the 16th of July, a hurricane burst upon the devoted ship which carried them, and the three perished in the waves. Her memoirs were published by Emerson and Channing under the title of *Memoirs of Margaret Fuller, Marchesa Ossoli* (London, 1852).

FULLER, THOMAS, D.D., an eminent English historian and divine, was born in 1608 at Aldwinkle, Northamptonshire, of which parish his father was rector. He was educated at Queen's College, Cambridge, and greatly distinguished himself by his application to study. He took the degree of A.B. in 1624, and that of A.M. in 1628. He stood so high in the estimation of his college that, before he was 23 years of age, he was appointed to St. Benets, Cambridge, and acquired great popularity as a preacher. Soon after, he was collated to a prebend in Salisbury Cathedral, and obtained a fellowship in Sidney Sussex College. His first publication was a poem, entitled *David's Heinous Sin, Hearty Repentance and Heavy Punishments* (1631, 8vo.). He was next presented to the rectory of Broad Windsor, Dorsetshire; published his *History of the Holy War at Cambridge* in 1639; and in 1640 removed to London, where he was chosen lecturer at the Savoy Church in the Strand.

The same year, he was a member of the Convocation at West-

minster, and one of the select committee appointed to draw up new canons for the better government of the church. During the civil war he adhered firmly to the royal cause; and shared in its reverses. In 1546, however, he was chosen lecturer, first, at St. Clement's Lane, Lombard Street, and afterwards at St. Bride's. About 1648, he was presented to the living of Waltham, in Essex. In 1650, he published a geographical account of the Holy Land, entitled *A Pisgah sight of Palestine and the Confines thereof* (folio, with maps and views), and *Abel Redivivus*, a collection of lives of modern divines. In 1655, he published at London *The Church History of Brittain from the Birth of Jesus Christ until the year 1648* (folio). In 1658, he received the living of Cranford, Middlesex, and at the Restoration he was reinstated in his prebend of Salisbury, of which he had been deprived by the Parliamentarians. He was also appointed chaplain extraordinary to the king, and created D.D. at Cambridge by royal mandamus. He died August 16, 1661. His principal work, *The Worthies of England*, was published at London in 1662 (folio). Valuable for the information it contains on provincial history, it abounds in biographical anecdote, witty remark, and acute observation on men and manners. A new edition with his life prefixed, appeared in 1810 (2 vols. 4to). His *Holy and Profane States* were republished in America in 1831. Quaint humor is one of F.'s peculiar characteristics; but his writings are no less remarkable for wisdom, imagination, and, when occasion demands, even for pathos. 'Next to Shakspeare,' says Coleridge, 'I am not certain whether Thomas Fuller, beyond all other writers, does not excite in me the sense and emulation of the marvelous. . . . He was incomparably the most sensible, the least prejudiced great man, in an age that boasted of a galaxy of great men.'

FULLER'S EARTH, a mineral consisting chiefly of silica, alumina, and water, with a little magnesia, lime, and peroxide of iron. The silica is about 50, the alumina 20, and the water 24 per cent. of the whole. It is regarded as essentially a hydrous bisilicate of alumina. It occurs in beds, associated with chalk, oolite, &c.; is usually of a greenish-brown or a slate-blue color, sometimes white; has an uneven earthy fracture, and a dull appearance; its specific gravity is from 1.8 to 2.2; it is soft enough to yield readily to the nail; is very greasy to the touch; scarcely adheres to the tongue; falls to pieces in water, but does not become plastic. It has a remarkable power of absorbing oil or grease; and was formerly very much used for fulling cloth (see **WOOLLEN MANUFACTURE**), for which purpose it was considered so valuable, that the exportation of it from England was prohibited under severe penalties; it is still used to a considerable extent. The annual consumption in England is said to have at one time exceeded 6000 tons. It is found at Nutfield, near Reigate, in Surrey, in cretaceous strata; where there are two distinct beds, the upper one of a greenish color, and 5 feet thick, resting on the other, which has a bluish tint, and is 11 feet thick. It is also found in Bedfordshire, Nottinghamshire, and Kent; and on the continent in Saxony, Bohemia, and near Aix-la-Chapelle. There is a considerable deposit of it at Bath, where the group of associated blue and yellow clays and marl has received the name of 'the Fuller's Earth Series.' It is also found at Maxton, in Scotland.

FULMAR, or **FULMAR PETREL** (*Procellaria* or *Fulmarus*), a genus of birds generally referred to the gull family (*Laridae*),

Northern Fulmar (*Procellaria glacialis*).

and containing some of the most strictly oceanic birds. See **PETREL**. The bill is not longer than the head—large, strong, and subcylindrical; the upper mandible suddenly hooked at the point; the lower mandible with the tip curved upwards; the tips of both mandibles appearing as separate pieces firmly joined to the straight part of the bill, which is marked by longitudinal grooves;

the nostrils enclosed in a tube open at the extremity, and extending along the ridge of the upper mandible. The tarsi are compressed; the hind-toe rudimentary, a mere claw. The tail is short, and slightly rounded; the wings are long.—The **COMMON** or **NORTHERN F.** (*P.* or *F. glacialis*) is a bird about the size of a duck, gray above, white beneath, the head and neck pure white, the tail white, the bill yellow; the young brownish gray. It inhabits the most northern seas, in which its numbers are prodigious; breeds on the rocky shores of the Farøe Islands, Iceland, Greenland, Spitzbergen, &c., on the grassy shelves of the precipices, making a slight nest or a mere excavation, in which it lays one egg. It is rarely to be seen on the southern coasts of Britain, but more frequently in Orkney and Shetland, where, however, it does not often breed, although it breeds in great numbers in St. Kilda and the adjacent islets of Borrera and Soa. It greatly frequents these isles, and is of importance to the inhabitants of St. Kilda, who esteem its eggs and flesh above those of any other bird, and seek them in the most perilous manner, descending by ropes from the summit of the precipices. The fulmars are also valued for their feathers, for their down, and for their oil, which is one of the principal products of St. Kilda, and is obtained from their stomachs. The old are said to feed the young with it; and when they are caught or assailed, generally lighten themselves by disgorging it. It is amber-colored, and has a peculiar and very disagreeable odor. Fulmars feed on all animal substances which come in their way, giving an evident preference to fat, and delighting in the blubber of whales. They pursue whales to prey on the cirrhopods which are attached to them, or imbedded in their skin. Multitudes of them gather around a dead whale, and they are so bold as to advance within a few yards of the men who are cutting it up. When food is abundant, they often glut themselves till they are unable to fly. They follow the greasy track of a whaler, and, indeed, some of them are always in attendance on ships immediately after they pass north of the Shetland Islands, ready to seize any garbage that may be thrown overboard. Sailors often amuse themselves in catching them by means of lines and hooks baited with fat.

Another species of *F.* (*P.* or *F. Pacifica*) exists in the Pacific Ocean, and the **MOTHER CAREY'S GOOSE** of sailors, a large bird of the southern seas, is sometimes referred to the same genus.

FULMINATE OF MERCURY, or **FULMINATING MERCURY** ($2\text{HgO}, \text{C}_4\text{N}_2\text{O}_2$), is best prepared by dissolving 3 parts of mercury in 36 of nitric acid of specific gravity 1.34, without the application of heat, in a flask capable of holding 18 times the bulk of the acid. The solution is then to be poured into a large vessel containing 17 parts of alcohol of specific gravity 0.830, and immediately to be re-transferred to the flask, which is still full of nitrous vapors, and with which it must be well shaken, in order to effect their absorption. Effervescence commences in a few minutes, and soon becomes extremely violent; and at the same time there is a deposit of metallic mercury, which is gradually re-dissolved. The reaction must be moderated by the gradual addition of 17 parts more of alcohol; and on cooling, crystals of the fulminate, amounting to 4.6 parts, are deposited. These must be washed with cold water, and dried at 100°F . Fulminate of mercury forms white silky needles. It may be handled without much danger when moist; but when dry, it explodes with violence when struck by a hard body, or when touched with nitric or strong sulphuric acid. A mixture of 1 part of this salt with 6 parts of nitre, or of 3 parts of the fulminate, 5 of chlorate of potash, 1 of sulphur, and 1 of ground glass, is employed as the priming of percussion-caps. It is applied as a dry powder, and is made to adhere to the cap by the application of a drop of shell-lac varnish.

FULMINATE OF SILVER, or **FULMINATING SILVER** ($2\text{AgO}, \text{C}_4\text{N}_2\text{O}_2$), is prepared in nearly the same manner as the fulminate of mercury. It is more powerfully explosive than the last-named salt. Even when moist or under water, pressure with a hard body will cause its explosion; and when quite dry, the slightest friction between two hard bodies produces a similar result.

The preparation of the fulminates is attended with very considerable danger, and should be attempted by none but professed chemists.

FULMINIC ACID has never been isolated in the hydrated form, but from the composition of its salts, its formula doubtless is $2\text{HO}, \text{C}_4\text{N}_2\text{O}_2$. It is thus isomeric with cyanic acid. Fulminic acid may be separated from the oxide of mercury and silver, and combined with other bases, such as potash; and all such compounds are more or less explosive.

FULTON, **ROBERT**, a celebrated American engineer, was born at Little Britain, Pennsylvania. His parents belonged to Ireland, whence they emigrated to America; and being in poor circumstances, all the education young F. acquired was the ability to read and write. He made good use, however, of what he had acquired, and passed in study the time allowed him for recrea-

tion. When he was old enough, his mother apprenticed him to a jeweler in Philadelphia. In addition to his labors at this trade, he devoted himself to painting; and the sale of his portraits and landscapes enabled him, in the space of four years, to purchase a small farm on which he placed his mother, his father being dead. At the age of 22 he proceeded to London, where he studied painting under West; but after several years spent thus, he felt that this was not his true vocation. Accordingly, abandoning painting, he applied himself wholly to mechanics. Some works he performed in Devonshire obtained him the patronage of the Duke of Bridgewater, and likewise that of the Earl of Stanhope.

In 1794, he obtained from the British government a patent for an inclined plane, the object of which was to set aside the use of locks; and in the same year, he invented a mill for sawing and polishing marble. His next invention was a machine for spinning flax, followed by one for making ropes. He was received as a civil engineer in 1795; and wrote a work on canals, in which he developed his system. Accepting an invitation from the United States minister at Paris, he proceeded to that city in 1793, and remained there for seven years, devoting himself to new projects and inventions. Amongst his inventions here was the *nautilus* or submarine boat, intended to be used in naval warfare, which he in vain sought the French government to accept; nor was he more successful with the British government, which he next tried, though commissions were appointed in both cases to test the value of his invention. Having failed in this matter, he next turned his attention to a subject that had frequently occupied his mind before, and about which he had written a treatise in 1793—viz., the application of steam to navigation. In 1803, he constructed a small steamboat, and his experiments with it on the Seine were attended with great success. Disgusted with the reception he met, he returned in 1806 to New York, and pursued his experiments there. He perfected his *Torpedo* (q. v.) system, which was afterwards employed effectively in the war between Britain and America. In 1807, he launched a steam-vessel upon the Hudson, which made a successful start, in the presence of thousands of astonished spectators. From this period, steamers (for the construction of which F. received a patent from the legislature) came into pretty general use upon the rivers of the United States. Although F. was not the first to apply steam to navigation, as a steam-vessel had been tried upon the Forth and Clyde Canal as early as 1789, yet he was the first to apply it with any degree of success (see STEAM-NAVIGATION). His reputation was now firmly established, and he was employed by the United States government in the execution of various projects with reference to canals and other works. In 1814, he obtained the assent of the legislature to construct a steam-frigate, which was launched in the following year. Though the labors of F. were attended with such great success, various lawsuits in which he was engaged in reference to the use of some of his patents, prevented him from ever becoming wealthy; and anxiety, as well as excessive application, tended to shorten his days. His death in 1815 produced extraordinary demonstrations of mourning throughout the United States. F. had married, in 1806, a niece of Robert Livingston, U. S. minister in France.

FUM, or, more properly, FUNG—the first being the Portuguese pronunciation of the word; the Chinese Phoenix—one of the four symbolical animals supposed to preside over the destinies of the Chinese empire. Its appearance indicates an age of universal virtue, the influence of which has extended throughout creation. It is supposed to originate from the element of fire, and to be born in the Tan-Henē, or Hill of the Fiery Halo of the Sun; to have the forepart of a goose, hind-quarters of a stag, neck of a snake, fish's tail, fowl's forehead, down of a duck, dragon's marks, the back of a tortoise, face of a swallow, and beak of a cock, with beak, claws, and feathers of various colors, red crest, and golden beak. It is about six cubits high, and comes from the East.

In mystical language, it is called the Leih-kwan, or 'mandarin of time,' and it is said to have a forehead like heaven, eyes like the sun, back like the moon, wings like the wind, feet like earth, and a tail like the planets. On its body are inscribed the five cardinal virtues. According to some authors, it only perches on the woo-tung tree, and eats the seeds of the bamboo; others describe it as swallowing small carp. Other accounts say it eats no living insect, and treads on no growing plant. Its voice is said to be like a flute, drum, or even thunder. When seen, it is followed by birds. According to Chinese history, it has occasionally appeared; and a celebrated female flute-player, named Lung-yn, is said to have enticed it from heaven with her music, and then fled away with it. Like the phoenix of the Egyptians and roe of the Arabs, the bird may have had a historical origin, subsequently disfigured by fiction. It is often represented on Chinese works of art, under the form of a gallinaceous bird, and is embroidered on the dresses of mandarins of a certain rank. It is mentioned by some modern English poets.—Kidd, *History of China*, p. 267; Ching-tsze-tung, 172 sect.; Yuen-keen-luy-han, 148 sect.

FU'MAGE, in the Law of England, was properly smoke-farthing, or a customary payment for every house that had a chimney or fire-hearth. This tax is mentioned in Domesday as paid by custom to the king for every chimney in the house. Edward the Black Prince is said to have imposed a tax of a florin for every hearth in his French dominions. The first statutory enactment on the subject in England is by 13 and 14 Car. II. c. 10, whereby a tax of 2s. on every hearth in all houses paying to church and poor was granted to the king for ever. This tax was abolished 1 William and Mary, st. 1. c. 10.

FUMARIA'CEÆ, a natural order of exogenous plants; herbaceous, with a watery juice; their leaves alternate, much divided; the calyx of two deciduous sepals; the corolla of four very irregular petals; the stamens sometimes four and distinct, more generally six and in two bundles; the ovary free, one-celled, one-seeded, or many-seeded; the seeds having large albumen. The F. are regarded as in their botanical characters approaching most nearly to the *Papaveraceæ* (Poppy, &c.); but their general aspect is very different, and they do not possess the same powerful properties. Both the foliage and flowers of some have considerable beauty. *Dielytra spectabilis* is a well-known favorite in gardens and green-houses. More than one hundred species are known, mostly natives of temperate climates in the northern hemisphere. Several species of *Fumaria* and *Corydalis* are natives of Britain. The COMMON FUMITORY (*Fumaria officinalis*) is a very frequent weed in gardens and cornfields, but of rather delicate and beautiful appearance. It is annual, and easy of extirpation, where it springs up in excessive abundance. It was formerly much employed in medicine, having a high reputation as a tonic and diaphoretic, and although disused in Britain, is still esteemed in France as a remedy in scorbutic affections, chronic eruptions, &c. Some of the other species of fumitory possess similar properties. The leaves have an intensely bitter saline taste.

Common Fumitory (*Fumaria officinalis*).

It is annual, and easy of extirpation, where it springs up in excessive abundance. It was formerly much employed in medicine, having a high reputation as a tonic and diaphoretic, and although disused in Britain, is still esteemed in France as a remedy in scorbutic affections, chronic eruptions, &c. Some of the other species of fumitory possess similar properties. The leaves have an intensely bitter saline taste.

FUMA'RIC ACID, known also as Boletic Acid ($2\text{H}_2\text{O}, \text{C}_4\text{H}_2\text{O}_4$), is of frequent occurrence in the vegetable kingdom. It was first obtained by Braconnot from a species of boletus, and has since been found in many other fungi, in numerous lichens, in various species of *Fumaria*, in *Corydalis bulbosa*, &c.

Fumaric acid may also be obtained, in association with malæic acid, by heating Malic Acid (q. v.) to 350°F .

It crystallizes in prisms, which have a very acid taste, are only slightly soluble in water, but dissolve readily in alcohol and ether. At a temperature of 392°F , it volatilizes without fusing, and is converted into the malæic acid already mentioned, which possess the same composition as fumaric acid, but different properties. If malæic acid is exposed for a long time to a temperature of 266° , it again passes into fumaric acid, so that these acids are mutually convertible.

Kekulé has shown (*Annalen d. Chemie*, 1861) that both fumaric acid and malæic acid combine directly with bromine, and produce crystals of dibromo-succinic acid; and further, that if fumaric acid be dissolved in water, and digested with an amalgam of sodium, the nascent hydrogen from the decomposed water combines with the acid, and converts it into succinic acid. Its compounds are of no special interest.

FU'MIGATING PA'STILS are composed of various ingredients, which, by their smouldering combustion, evolve agreeable odors. The following recipe for their composition is given in the *Württemberg Pharmacopie*: Take of benzoin and dry balsam of Peru, each 16 parts; of yellow sandalwood, 4 parts; of labdanum, 1 part; of charcoal from lime-tree wood, 96 parts; of nitrate of potash, 2 parts; and of mucilage of tragacanth, enough to form the mixture into a paste, from which conical pastils are to be made by a small mould.

The 'Ribbon of Bruges' is also employed for aromatic fumigation in the same manner as pastils. It is prepared as follows: Dissolve two ounces of nitrate of potash in a pint of water; in this fluid, steep good undressed cotton-tape, and hang it up to dry. Prepare a tincture composed of spirit, half a pint; musk, half an ounce; otto of roses, one drachm; benzoin, four ounces; myrrh, half an ounce; orris-root, half a pound. When this tincture has stood for a month, steep the prepared tape in it. The

tape when dried is fit for use. Light it, blow out the flame; and as it smoulders, a fragrant vapor will rise into the air. For further information on this and allied subjects, see Piesse's *Art of Perfumery*.

FUMIGATION (Lat. *fumigatio*, from *fumus*, smoke), the cleansing or medicating of the air of an apartment by means of vapors, employed chiefly for the purpose of detaching infectious poisons from clothing, furniture, &c. See **CONTAGION**, **INFECTIO**. Most of the methods of fumigation formerly employed have little real value, and are to be looked on chiefly as grateful to the senses; as, for instance, the burning of frankincense, camphor, &c. The really active processes are noticed under the article **DISINFECTANTS**.

FUNARIA, a genus of Mosses, with terminal fruit-stalks, and oblique double peristome, both the inner and outer having sixteen teeth. A few species are found in Britain, one of which, *P. hygrometrica*, is an object of particular interest on account of the hygrometric properties of its fruit-stalk, which, if moistened in the lower part, twists several times round in one direction, and if moistened in the upper part twists several times round in the opposite direction. This is owing to a peculiar arrangement of the cellular tissue, which is spiral in one direction at the base of the stalk, then straight, then spiral in the opposite direction. The structure of the fruit-stalk has been closely examined and commented on by Dr. Lankester (*Annals of Nat. Hist.* vol. iv.). *P. hygrometrica* has very concave, ovate, entire, apiculate leaves. It is very common on old buildings and on dry barren soils; and is said to be almost always found where a wood-fire has been burning on the ground, as on the site of gipsies' encampments, &c.

FUNCHIA'L, the capital and the only town of the island of Madeira (q. v.), is situated on the south side of the island, and consists chiefly of one street, extending for about a mile along the shore, and of numerous streets and lanes at right angles with the main street, and leading up the hill which backs the town. Its roadstead is open, and its anchorage rocky and uneven. F. has a cathedral, numerous churches, and small convents, and is defended by four forts. From it all the produce of the island is exported. Pop. (1178) 20,606.

FUNCTIONS, a mathematical term. When two or more variables are combined with constants in an equation, and are such that a change of value of one implies a corresponding change of value of one or more of the others, then such variables are said to depend on, and to be functions of each other; and the expression of the mode of dependence is said to be a *function* of such variables. If such an expression involves but one variable, it is said to be a function of one variable; if two are involved, to be a function of two variables; and so on. Thus $\sin x$, e^{ax} , $\log. x$, $\sqrt{a^2 - x^2}$ are functions of one variable—viz. of x ; e^{ax+by} , $\tan(ax+by)$, xy , are functions of two variables, x and y ; so xyz , $x^2 + y^2 + z^2$ are functions of three variables, and so on. Functions are denoted by the symbols, F , f , ϕ , ψ , &c. Thus $F(x)$ means a function of one variable, x , combined with constants or not, as the case may be; $\psi(xyz)$ a function of three variables. These functional symbols are *general*, and their specific forms are the particular functions which arise from operations in algebra, trigonometry, &c.

Functions are implicit or explicit. When one variable is expressed in terms of others, it is said to be an explicit function of them; but when all the variables remain involved in one expression, the function is said to be implicit. Thus, $x^2 + y^2 - r^2 = 0$ is an implicit function of two variables, but $y = \sqrt{r^2 - x^2}$ is an explicit function of one variable. In explicit functions, the variable which is expressed in terms of the others is called the *dependent* variable, and the others the *independent* variables. Explicit functions are usually written in the form $z = f(xy)$; implicit in the form $u = F(xyz) = 0$. Functions, again, are algebraical or transcendental. Algebraical functions are those which involve the operations of addition, subtraction, &c., and of involution and evolution. Transcendental functions are those where the operations symbolized are such as e^x , $\log. x$, $\sin x$, &c.—i. e., exponential, logarithmic, or circular. Functions, also, are simple or compound according as they involve one or several operations. $y = \sin x$ is a simple function; but $y = \log. \sin x$ is compound. Further, functions are divided into continuous and the discontinuous, the circulating and the periodic. Continuous functions are such as are subject to the following conditions: 1. As the variable gradually changes, the function must gradually change; 2. The law symbolized by the functional character must not abruptly change. Circulating functions are those whose values lie within certain limits for all values of the variables. $y = \sin x$ is an example at once of a continuous and of a circulating function. A function is said to be periodic when it takes the form $f^n(x) = x$

signifying that if on x the operation f be performed n times, the resulting value will be x . Thus, $f(x) = \frac{1}{1-x}$ is a periodic function of the third order. For performing the operation indicated by f the second time on $\frac{1}{1-x}$ as the variable, we have $f^2(x) = \frac{1}{1 - \frac{1}{1-x}} = -\frac{1-x}{x}$; and the third time we have $f^3(x) = \frac{1}{1 - (-\frac{1-x}{x})} = x$. The functional calculus is a recent growth of

the transcendental analysis. The object of the Differential Calculus (q. v.) is generally to ascertain the changes in functions arising from the continuous and infinitesimal variation of their subject variables. The object of the new functional calculus is, speaking generally, to investigate the forms of functions and their growth, when they are subject to a continuous and infinitesimal change as to form. According to Mr. Price (treatise on the Infinitesimal Calculus), as the differential calculus investigates properties of continuous numbers, so does the new calculus the properties of continuous functions; and as there is an integral calculus of numbers, so there is an inverse calculus of functions. Of the new calculus, the Calculus of Variations (q. v.) may be considered the main branch. It includes, of course, the subject of functional equations. Functional equations are those in which it is required to determine from equations the forms of functions entering them; e. g., what is the function of x and y which satisfies the equation $f(x) \times f(y) = f(x+y)$? See article **CALCULUS OF FUNCTIONS** in the *Encyclopædia Metropolitana*.

FUND, FUNDING SYSTEM. Fund (Lat. *fundus*, ground, foundation) means a supply of money or a source whence money may be obtained. When we speak of 'the funds' in this country, we mean that great organization for buying and selling the right to become a public creditor, and receive a share of the interest of the national debt. See **DEBT, NATIONAL**. When money has in this country been borrowed for public purposes, and it has been found that it cannot be repaid as a temporary loan, the resolution to hold it as a perpetual loan at a certain interest has been called 'funding' it; and hence we read from time to time that certain obligations were converted from floating into funded debts.

FUND, SINKING, a plan pursued for a considerable period for the purpose of collecting money for the payment of the national debt of Great Britain. It was begun in 1716 by Sir Robert Walpole. Certain taxes which had previously been laid on for limited periods were then rendered perpetual, for the purpose of paying the interest of the funded debt. They produced more than enough for this purpose, and the surplus was laid aside, that it might accumulate into a fund for extinguishing the debt. It appeared to operate well, since, in 1728, after it had existed for twelve years, debt was wiped off to the extent of £6,648,000. It was not observed that, during the wiping off, new debt had been created to about the same extent, so that the nation was just in the position in which it would have been had it neither borrowed nor repaid. It is supposed that Sir Robert may have seen the fallacy of the sinking fund, since in 1732 he took half a million from it to meet the expenditure of the year, instead of raising a new loan. It was in 1786, however, that the system was established on a great scale by the younger Pitt, who, notwithstanding his great practical abilities, was entirely misled by the theories of Dr. Price in his work on Annuities. The system continued to be conducted on an enormous scale, until another student of economy and figures conclusively proved it to be useless; this was accomplished in 1813 by Dr. Hamilton, in his *Inquiry concerning the Rise and Progress, the Redemption and Present State, and the Management of the National Debt of Great Britain*. The fallacy which Dr. Hamilton showed to pervade a sinking fund may be best explained by a single example. Suppose that one requires to borrow £100, and lays by £5 a year as a fund to pay it up with. Accumulating at compound interest, this fund will pay back the loan in about fifteen years. The borrower will, however, gain no more by the process than if he paid the £5 a year to his creditor, for his debt would be diminishing to precisely the same extent as the fund to pay it off would be increasing.

Suppose that while requiring only £100, the borrower raises £200, and lends out one of them, accumulating the interest until the whole amounts to £200; the borrower will no doubt be receiving interest on £100, but he will be at the same time paying interest on £200; and he would repay his debt at the same cost and with more simplicity if, instead of borrowing the second hundred at 5 per cent., he paid over £5 a year to his creditor. In these instances, nothing is lost by the sinking fund. But suppose that in the last case the creditor had agreed to lend the £100 at 5 per cent., but in consideration of the greater risk, would not lend

the £200 at less than 6 per cent., while the borrower can only get 5 per cent. for the half which he relends—here the transaction would cause a dead loss of £2 a year over the plan of repaying by instalments. This was exactly the case with the British sinking fund. The more money the chancellor of the exchequer wanted, the higher were the terms demanded by the lenders, and the addition to each loan for setting aside a sinking fund increased the rate of interest paid on it.

FUNDAMENTAL BASS, in Music, is the root or fundamental note of the harmony. See HARMONY.

FUNDI, or **FUNDUNGI** (*Paspalum exile*), a kind of grain much cultivated in the west of Africa. It is allied to the millets, and still more nearly to some of the kinds of grain cultivated in India. See PASPALUM. It is wholesome and nutritious, and has been recommended to attention in Britain as a light and delicate food for invalids. The natives of Western Africa throw it into boiling water, pour off the water, and add palm-oil, butter, or milk. By Europeans and negroes in Sierra Leone, it is much used with stewed meat, and sometimes made into porridge with milk.

FUNDY BAY, an arm of the Atlantic, separates Nova Scotia from New Brunswick and the state of Maine. With an average breadth of 35 miles, it extends 180 miles in length from north-east to south-west. It forks, at its head, into two inlets, the northern called Chignecto Bay, and the southern, Minas Channel, which are divided by narrow necks of land from the Gulf of St. Lawrence. Along its north-west side, reckoning downwards, it receives the St. John, which is the principal river of New Brunswick, and the St. Croix, which, through its entire course, forms the international boundary. The navigation is rendered perilous by the peculiarity of the tides, which are said to rise and fall fully 70 feet.

FUNERAL EXPENSES, in Law. If limited to the degree and quality of the deceased, funeral expenses are a privileged debt, allowed before all other debts and charges, both in England (3 Inst. 202) and in Scotland (Stair, iv. 35, 3). If the parties primarily liable neglect the duty of giving decent burial to the dead, a stranger may do so, and claim reimbursement out of his effects before all others having right, whether heirs or executors; yet this was not clear until very recently in the law of England. There is no fixed sum allowed in English practice, but if one dies in debt, it is usual to restrict the funeral expenses to £10. As against legatees, more liberal sums are allowed. In Scotland, it is held (Buchanan v. Ferrier, 14th February 1822) that mourning for the widow and such of the children of the deceased as were present at the funeral is a valid charge; but the reverse is the case in England, it having been decided (Johnson v. Baker, 2 C. and P. 207) that the widow has no claim for mournings either against the executor or the creditors of her husband. All along there seems to have been rather greater liberality in this matter in Scotland than in England, where Lord Holt held that nothing was allowable against a creditor except for the coffin, ringing the bell, parson and clerk (1 Salk. 296).

FUNERAL RITES. The methods of disposing of the dead have been so various, and connected with so many ceremonial observances dictated by affection, religious conviction, or superstition, that a full consideration of the subject would occupy a volume. Under the article BURIAL will be found a description of the principal modes of interment, and the accompanying funeral rites of the ancients.

With the spread of Christianity came the decorous interring of the dead with religious ceremonials indicative of hopes of a blessed resurrection. From the moment of death until interment, the body is the object of solemn ceremonial in the Roman Catholic Church. At death, a crucifix is placed in the hand, or at the feet, and holy-water is sprinkled. The chief funeral rites are solemnized in the church, into which the coffin is borne and placed on a bier. Throughout France, the Netherlands, and continental Europe generally, the ordinary cortege of a funeral is a hearse with a bier, on which is the coffin, covered with a pall, followed by carriages all in black, with black horses. The same arrangement is pursued in England, but the hearse, sometimes over-decorated with dark plumes, is closed instead of being open. In the more common class of funerals, the coffin shrouded in a pall, is borne on spokes, or on the shoulders of bearers. All the attendants are in black. A certain etiquette as to pall-bearers (parties who hold ribbons attached to the pall) is observed; the relatives of the deceased taking their place nearest the head in the degree of consanguinity, and the same arrangement is maintained in lowering the coffin by cords into the grave. Only in exceptional cases are bodies put in leaden coffins and deposited in vaults; the common sense of the people now appreciating the propriety of allowing corpses to dissolve and mingle with the earth of the grave; and for this practice, the numerous new cemeteries offer facilities. Scottish Presbyterians, as in the case with some English dissenters, have

no funeral-service, unless we reckon as such a prayer, and occasionally the reading of a chapter of Scripture, by a clergyman before the body is borne from the house; but in other respects the Scottish ceremonial differs little from the English. Formerly, in the case of important personages, the hearse was preceded by a class of undertaker's men to clear the way, designated *saulies*, and gumpheon-men—these last bearing a pole shrouded at the top with black silk, called a gumpheon (*gonfalone*, a banner), being a relic of an ancient heraldic ceremonial; but this custom has nearly, if not altogether, disappeared. At Scotch funerals, the relatives, and in some cases the friends of the deceased, wear white cambric *weepers* at the wrists. Till within the present century, there was a practice of giving a series of expensive entertainments to guests at Scottish funerals, beginning with the *lykwake*, and ending with the *dredgy* (dirge); but all this is gone, or nearly so. The giving of costly entertainments was not, however, confined to Scotland, or to Ireland.

Taking its rise in ancient customs which were perpetuated by the Anglo-Saxons, the practice of consuming meat and drink in a species of gloomy festivity at funerals was common in England, and carried to an extravagant length at the decease of persons of distinction, on which occasion Doles (q. v.) were also given. It had even its counterpart in the usages of the ancients. The *nekrodeipnon*, or funeral-banquet, is mentioned by Lucian and Cicero. It was always celebrated in the house of the nearest relative of the deceased, and Demosthenes, the patriot orator of Greece, tells us in his Oration, *On the Crown*, that the relatives of those who were slain at Chaeroneia, were entertained by him in his own mansion, as if he were the nearest kinsman of the fallen heroes. The *nekrodeipnon* is often represented on funeral monuments. For some curious information respecting old funeral entertainments, we refer to Brand's *Popular Antiquities*, edited by Ellis. Without losing as regards decorum, funeral arrangements have been greatly cheapened in most large towns in England and Scotland by means of funeral-conducting establishments belonging to societies or private speculators.

FÜNFHAUS, **FÜNFHÄUSEL**, or **HA'NGENDENLISSEN**, a town of Austria, about two miles north from Vienna, of which it is a suburb. It has silk, satin, woollen, cotton, and red leather manufactures. Pop. (1880) 39,967.

FÜNFKIRCHEN ('Five Churches'; Hungarian, *Pees*), an important town of Hungary, capital of the county of Baranya, is situated on the southern slope of the Mecseg Mountains, near the Slavonian boundary, 105 miles south-south-west of Pesth. It is the seat of a bishop, and is one of the oldest, as well as one of the most pleasantly situated and beautiful towns of Hungary. It formerly possessed a university. The most important of its buildings are the large and imposing cathedral, the bishop's palace, an Italian structure, the town-house, lyceum, gymnasium, seminary, and the churches, which are numerous and beautiful. It has important tanneries, woollen and flannel weaving and silk-spinning; produces wine, fruit, and tobacco, has coal-mines and iron-works, and a flourishing trade in hogs and gall-nuts. Pop. (1880) 28,702.

FUNGI, an order of acotyledonous or cryptogamous plants, containing a very great number of species, nearly 5000 being known, whilst it is probable that the whole number existing is very much greater. They are amongst the lowest forms of vegetable life, and some naturalists of no mean reputation have entertained the notion that they spring into existence in certain circumstances, not from germs previously existing, but from a mucus capable of organization, or through changes in the cells of more highly organized plants, and of animals in states of disease or of decay; an opinion which, however, is more generally rejected as having no foundation in accurate observation, as not necessary to explain the readiness with which certain fungi almost invariably spring up in certain circumstances—from which is derived the chief argument in its favor, as opposed to all analogy of ascertained facts, and as rendered improbable by the abundant provision which all the fungi possess for the perpetuation and diffusion of the species.

Fungi are cellular plants, the cells sometimes elongated so as to become filaments. They consist of a *thallus*, which spreads in a matrix, and is nourished by it, and from which stems are thrown up into the air, bearing the fructification. The organs connected with fructification are often the principal part of fungi, and the thallus very small, consisting of a few cottony threads, or closely compacted cells, or even altogether undiscernible. Not unfrequently, however, the proportion of the thallus is comparatively great, and in circumstances unfavorable to the development of the organs of fructification, it extends itself greatly in the matrix, as in the case of Dry Rot, Ergot, &c. (q. v.) and even of the common mushroom. The thallus of fungi is called *mycelium* (Gr., *mykes*, a mushroom), and in mushrooms and some other kinds is further popularly known as the *spawen*. Fungi are nearly related to algæ and to lichens, but differ from both in deriving their nourishment

from the earth or from the bodies upon which they grow, not from the medium by which they are surrounded. They differ also from lichens in their generally much softer substance and their fugacious character; also in being quite destitute of green granules (*gonidia*) in the thallus, which are characteristic of that order. They differ from algae in not living immersed in water or other liquid, but producing their fructification in air. The lowest forms of fungi, and the lowest forms of algae, are sometimes, however, not easily distinguished; and the mycelium of some fungi is capable of spreading in a liquid, and assuming a modified appearance extremely resembling that of some algae. It is supposed to be the presence of the *mycelium* of certain fungi which makes liquors 'mothy'; and to a similar cause is ascribed the ropiness of the dough in some bakehouses, an evil not easily cured.—From other plants in general, fungi differ in their chemical composition, which is remarkably nitrogenous, and assimilates them to animal organisms; whilst unlike other plants, they do not absorb carbonic acid from the air, and give out oxygen, but, like animals, absorb oxygen, and give out carbonic acid; so that some naturalists have proposed to constitute for them a distinct kingdom of nature intermediate between the animal and the vegetable.

Fungi are very various in size, many being scarcely visible without a microscope, whilst others are some feet in diameter. Even the same species, however, often exhibits great variety, not only in size, but in other particulars, according to the different circumstances of its growth, causing great difficulty to the botanist, whilst further difficulty arises from the modifications of imperfectly developed mycelium, of which many spurious genera have been constituted. A great resemblance in general appearance to fungi is sometimes exhibited by diseased portions of leaves, &c., and by the secretions caused by the attacks of insects.

When the spore (seed) of a fungus germinates, it sends out radiating filaments, which generally branch and interlace, and portions of this mycelium removed to another favorable situation, grow there, so that fungi are propagated by this means as higher plants are propagated by their tubers or by the division of their roots.

The fungi of simplest structure or lowest organization consist of nothing more, when they have reached their fullest development, than masses of spheroidal cells, spores, breaking up into a fine powder, as in some of the small parasitic species which are very injurious to corn. Sometimes these cells are united into jointed threads. In species of rather higher organization, the plant consists of jointed threads, but the spores are formed in the enlarged terminal joints, and are dispersed by their bursting. In the higher kinds, the spores are produced in or on peculiar organs of extremely various shape and character. In some, as puff-balls, the whole interior of the plant is filled with the fructification. In agarics, boleti, morels, &c., the fructification takes place on a particular membrane, a part of the external surface of the plant, called the *hymenium*, variously situated (in agarics on the under side of the *pileus* or cap), the extent of which is often greatly increased by wrinkles, plates or *gills*, pits, pores, &c. These form the highest division of fungi, called *Hymenomycetes*, in the system of Fries, the greatest continental authority in mycology, as this department of botany is sometimes termed. Berkeley, who, without any near rival, occupies the first place among the mycologists of Britain, divides fungi into two 'classes'; the first class not having the spores enclosed in tubular sacs (*asci*) or vesicles, and containing the 'orders' *Hymenomycetes* (agarics, boleti, &c.), *Gasteromycetes* (puff-balls, &c.), *Coniomycetes* (rust, smut, &c.), *Hyphomycetes* (mould, mildew, *botrytis*, *oidium*, &c.); the second class containing two orders, *Ascomycetes* (morels, truffles, &c.), in which the spores are definitely arranged in *asci*, and *Phycomycetes* (some kinds of mould, plants which grow on fermenting substances, and some of the minute pests of cultivated plants) in which the spores are in vesicles without definite arrangement.

Fungi generally grow in damp situations, but there are many which occur chiefly on dry soils or on dry substances; and some appear in their greatest perfection in the finest summer weather, although many are most abundant in the colder and moister seasons of the year. It has been commonly asserted that they abound more in the colder parts of the world than within the tropics, but it is not improbable that this opinion has its origin merely in imperfect observation of tropical species. The extreme rapidity of their growth, the briefness of their whole existence, the readiness with which they pass into decomposition, and the difficulty of preserving most of them in a form fit for examination, have been great obstacles to their scientific study. It is known, however, that some species are of very wide geographic distribution, whilst others are comparatively very limited. Some species grow in earth, others in various kinds of putrescent or fermenting animal or vegetable matter, many in decaying parts of trees or on dead wood, others on diseased animal and vegetable tissues, &c. It appears to be the office of many of them to hasten the decomposition of animal, and more particularly of vegetable

substances. Some of the minute kinds appear to be the cause of disease in the higher kinds of plants which they attack, and are formidable to the farmer and the gardener. Some are in like manner destructive to animal life, as in the case of the Muscardine (q. v.) or Silk-worm Rot, and certain species of *Spharia* which grow from living caterpillars. See *ENTOPHYTES*.

Some fungi are remarkably phosphorescent. Thus the undeveloped mycelium of some kind produces a very beautiful luminosity in some German coal-mines; and a species of agaric (*Agaricus Gardneri*), growing on palms in Brazil, shines brightly in the night. *Agaricus olearius*, a native of the south of Europe, is also luminous.

The chemical examination of fungi yields in large quantity a substance called *Fungine*, which, however, is now regarded as consisting of cellulose and fatty matter, several other nitrogenous substances, an acid called *Fungic Acid*, a kind of sugar, &c. The poisonous properties of some are ascribed to an alkaloid called *Amanitine*. Others appear to owe their poisonous character to an acrid volatile substance. Many of the smaller fungi are important because of the injury which they cause to crops, timber, &c. A few species are used in medicine, of which the only one really important is Ergot of Rye. One or two are used as tinder (see *AMADOU*), Moxa (q. v.), &c. The smoke produced by burning the dust (spores) of ripened puff-balls has anæsthetic properties, and is used for stupifying bees. *Polyporus squamosus* cut into slices makes the best of razor-strops. But the chief economical use of fungi is for food, and in the manufacture of the sauce called Ketchup (q. v.).

Edible Fungi.—Many fungi of the sub-orders *Hymenomycetes*, *Gasteromycetes*, and *Ascomycetes* are edible; and some of them are much esteemed as delicacies, whilst in many countries they constitute an important part of the food of the people. In Britain, very few are used, many of those species which are most esteemed on the continent of Europe being utterly disregarded, and indeed classed in popular estimation with toad-stools as poisonous. The truth appears to be, not that the greater number are poisonous, and only a few edible, but that the noxious species are comparatively few, the principal danger arising from the similarity of some of the poisonous and some of the edible agarics, and from the liability of some of the edible species to acquire poisonous properties in particular situations and circumstances. This is notably the case with the common mushroom (*Agaricus campestris*), which is far more generally used in Britain than any other edible fungus, but of which some varieties are unsafe, apparently in consequence of the circumstances of their growth. From the markets of Rome, and other cities of Italy, where numerous species of fungi are extensively sold, this species is rigorously excluded. So important an article of food are fungi in Italy, that in the market of Rome alone they are supposed to be sold to the value of about £4000 a year. For weeks, both in spring and in autumn, fungi form the principal and almost the sole food of multitudes of the poor in Italy, Germany, and France, and besides those which are eaten fresh, great quantities are used dried or preserved in oil, vinegar, or brine. The soaking of fungi in vinegar or brine takes away the acrid qualities of some which are dangerous when fresh, and renders them perfectly safe. So valuable are fungi esteemed, that some species are frequently cultivated.

The cultivation of the Common Mushroom (q. v.) is familiar to us in Britain, but other species of *Agaricus*, *Boletus*, &c., are plentifully raised in some parts of the continent of Europe, by watering the ground in places appropriate for them with water in which mature plants abounding in spores have been bruised; others are obtained by merely placing in favorable circumstances substances in which their spores are already contained. Thus, a species of *Polyporus*, much esteemed, is procured in Italy by moistening a porous stone (Ital., *Pietra funghia*) over which a little earth has been scattered; another species of *Polyporus* by slightly charring and then watering blocks of the wood of the common hazel; a species of *Agaricus*, by cutting off and then watering the heads of black poplar trees; and another *Agaricus*, by placing the grounds of coffee in circumstances favorable for its growth.

It is a common notion, but utterly destitute of foundation, that dangerous fungi may be distinguished from those which it is safe to eat by their discoloring a silver spoon if they are stirred with it whilst they are being cooked. Nor is greater dependence to be placed on the rule that the more readily deliquescent fungi are poisonous; nor on peculiarities of color of the flesh or juice, except in so far as these characters may avail for the discrimination of particular species, the qualities of which are known. The edible fungi have generally an agreeable smell and taste, whilst some of the poisonous kinds are offensive both to the nostrils and the palate, but no trustworthy general rule can be laid down on these points; and some of those which are very pungent and acrid when raw, become bland and wholesome when cooked, their acridity being dissipated by heat.

Among the most important edible fungi are:

Hymenomycetes.—The Common Mushroom, Champignon, and numerous other agarics and fungi closely allied to true agarics, as species of *Cortinaria*, *Cantharellus*, &c. These will be noticed in the article MUSHROOM.

Clavaria Botrytis.

divides into numerous small branches. It is said that all the species of this genus are esculent, although some are very superior to the rest in flavor and delicacy. One species (*C. flava*) is popularly known in Germany as *Ziegenbart* or Goat's-beard. They grow on the ground in woods and pastures.

Gasteromycetes.—Different kinds of Puff-ball (q. v.), in a young state, and whilst still fleshy throughout.

Ascomycetes.—Different species of Morel (q. v.), *Helvella* (q. v.), *Verpa*, *Peziza*, &c. The Common Truffle (q. v.), and allied species. *Cyttaria Darwinii*, which grows on living branches of South American beeches, and forms a principal part of the food of the natives of Tierra del Fuego during some months of the year.

It is a curious fact that the poisonous properties of mushrooms vary with climate, and probably with the season of the year at which they are gathered. Another circumstance deserving of notice is, that by idiosyncrasy some individuals are liable to be seriously affected even by those species which are usually regarded as innocent. Some species which are poisonous in this country, are used freely by the Russians; it appears they are in the habit of salting, boiling, and compressing them before they are eaten; and this may in some instances suffice to account for their having no noxious effects.

Symptoms and Effects.—The noxious species of mushrooms act sometimes as narcotics, at others as irritants. It would appear from the reports of several cases, that when the narcotic symptoms are excited, they come on soon after the meal at which the mushrooms have been eaten, and that they are chiefly manifested by giddiness, dimness of sight, and debility. The person appears as if intoxicated, and there are singular illusions of sense. Spasms and convulsions have been occasionally witnessed among the symptoms when the case has proved fatal. In some instances, the symptoms of poisoning have not commenced until thirty hours after the meal; and in these, narcotism followed the symptoms of irritation. It might be supposed that these variable effects were due to different properties in the mushrooms, but the same fungi have acted on members of the same family, in one case like irritants, and in another like narcotics. In most cases, recovery takes place, especially if vomiting be early induced. In the few instances which have proved fatal, there has been greater or less inflammation in the stomach and bowels, with congestion of the vessels of the brain.

Treatment.—The free use of emetics and castor oil.—Taylor *On Poisons*.

See Dr. Badham's *Treatise on the Esculent Funguses of Great Britain*; and *Fungi*, by M. C. Cooke, edited by Rev. M. J. Berkeley (1875).

FUNGIBLES. In the law of Rome, the contract of loan was divided into *mutuum* and *commodatum*, a division which has been adopted by the law of Scotland, and by most of the continental systems which are founded on the civil law. The former had reference to objects which admitted of being estimated by weight, measure, or number, or which could not be used without being given away or consumed. These objects, consisting of money, corn, wine, oil, and the like, could be used only by him who possessed the full right of ownership, and consequently the contract of *mutuum* transferred the ownership to the borrower, who became bound to return, not the object borrowed, but its equivalent. Objects of this nature, from the fact that they were got rid of one for another (*fungantur*), were called fungibles. The other class of movable objects, again, to which the Roman contract of *commodatum*, or hire, properly so called, applied, were transferred to the borrower on condition that he should return the same individual objects to the lender.

FUNGUS (Lat. a mushroom) is a term applied in pathology and surgery with several significations. Thus, any excrescence from a surface of skin, or mucous membrane, or even from deeper parts, is sometimes called a fungus, more especially if it have a soft mushroom-like character, and a broad short pedicle. When the pedicle is long and narrow, it is called *Polypus* (q. v.). The

growths to which the term fungus is chiefly applied are those which have the characters of Cancer (q. v.); especially *fungus hæmatodes*, a very dangerous variety. But fungus has yet another application in pathology, to those minute incrustations and alterations of the skin which are dependent upon the growth of vegetable parasites, as Favus, Ringworm (q. v.), &c.

FUNNEL (Lat. *funo*, to pour), in steam-vessels, is the iron tube designed to convey away above the deck the smoke and gases set at liberty during the combustion of fuel in the boiler-flues, and also, from its height, to afford a sufficient draught to the furnaces. In large ships, the funnel is of great size; and in men-of-war, usually telescopic, so that, by simple mechanism, it may be withdrawn during an action from the chance of injury by cannon-shot.

FUNNEL, a conical vessel terminating in a tube, and used for pouring liquids into narrow-mouthed vessels, and in laboratories for filtering. See **FILTER**. For common purposes, they are made of tin-plate or copper, but when for corrosive liquids, they are made of glass or earthenware. In some parts of Great Britain, as in the midland counties of England, a funnel is called a 'tundish;' in other parts, a 'filler.'

FUR is the term applied to the incrustation which is formed in the interior of vessels (tea-kettles, boilers of steam-engines, &c.) when calcareous water has been for a considerable time boiled in them. Many spring waters contain carbonate of lime held in solution by carbonic acid. When this water is boiled, the acid is expelled, and the carbonate is deposited, often in association with a little sulphate, forming a lining more or less coherent upon the sides of the vessel. In steam-boilers, this may be prevented by the addition of a small quantity of sal-ammoniac (hydrochlorate of ammonia) to the water; double decomposition takes place, carbonate of ammonia being formed and volatilized, while chloride of calcium remains in solution.

FUR AND FURRIERY. The skins of animals, having hair or fur as a coating, have been used in Europe as an article of clothing for many centuries. Since European countries, however, have become more and more cleared and inhabited, fur-bearing animals have nearly disappeared; and the supply is now chiefly obtained from other regions, especially North America.

All the chief fur-bearing animals will be found described under their proper headings: we shall do little more here than barely enumerate them. *Ermine* fur is of a pure white, except the tip of the tail, which is black. The spotted appearance of this fur is not natural; it is produced by sewing the black tail-tips on the white fur at certain spots. *Stoat* fur is a kind of inferior ermine. *Sable* fur, obtained chiefly from Northern Russia and Siberia, is valued in proportion to the darkness of its color.

Marten fur, especially that of a rich dark-brown olive color, is much sought for. *Fiery-fox* fur, brought chiefly from the north-eastern part of Asia, is admired both for its brilliant fiery color and for its fineness. *Red-fox* fur, differing in some particulars from the kind just named, is much sought after by the Chinese for trimmings, linings, and robes. *Silver-fox* fur has a peculiar lustrous silver-gray color. *Nutria* fur, belonging to the animal called the *coypou*, is brought largely from South America, chiefly as a cheap substitute for beaver. *Sea-otter* fur has been known in Europe about a century and a half, being obtained from the otters which frequent the seas washing the Asiatic shores of the Russian dominions; it varies from a beautiful brown to jet-black, and is very fine, soft, and glossy. *Seal* fur is obtained from the seals frequenting various coasts, chiefly in the Southern Ocean. *Beaver* fur was once much in request for the manufacture of hats; but the growing scarcity of the animal, and the substitution of silk hats for beaver hats, has lessened its importance. The fur of various other animals is similarly valued, either for its warmth or its beauty; such as that of the bear, racoon, badger, mink, lynx, musquash or musk-rat, rabbit, hare, squirrel, and chinchilla.

For manufacturing purposes, furs are classified into *felted* and *dressed*. Felted furs, such as beaver, nutria, hare, and rabbit, are used for hats and other felted fabrics, in which the hairs or filaments are made so as to interlace or entangle as to form a very strong and close plexus. The quality of the fur is better when the skin is taken from the animal in winter than in any other season, giving rise to the distinction between 'seasoned' and 'unseasoned' skins. The removal of the fur from the pelt is a necessary preliminary to the preparation of fur for felting purposes. In many kinds of skin, such as that of the hare, the fur is of two kinds—a close short layer of felting fur next the pelt, and longer outer hairs of unfelting fur. The removal of these two is affected separately. The long hairs are cut off by a kind of shears; and the true fur is then removed by the action of a knife, bearing some resemblance to a cheese-cutter, requiring much care in its management. In some sorts of skin, the long hairs are removed by pulling instead of shearing; in others, the greasiness of the pelt renders necessary a cleansing process before the shearing can be conducted, with the aid of soap and boiling water; and

In others, both pelt and fur are so full of grease as to require many repetitions of cleansing. For beaver skins, a machine of very beautiful construction is employed in cutting the fur from the pelt. When the coarse hairs have been removed to form a stuffing for cushions, the skin is placed in a machine containing a broad keen blade equal in length to the width of the skin. This blade has a peculiar reciprocating movement given to it, producing a kind of chopping effect on any substance to which it is applied, by coming nearly in contact with another blade placed parallel with it. The skin is guided between rollers into the space between the two blades; and then the action of the upper blade crops off the fur from the pelt in a very complete manner—every particle being removed, and yet the pelt is not cut. The fur falls upon an endless apron, which carries it to a chest, or trunk, containing a blowing-machine; this machine separates the fur into three or four qualities, by blowing to the furthest distance the lightest and most valuable filaments, leaving the heavier and coarser to be deposited sooner.

Furs have their felting property sometimes increased by the process of *carroting*, in which the action of heat is combined with that of sulphuric acid. The chief employment of felted furs is described under HAT MANUFACTURE.

Dressed furs are those to which the art of the *furrier* is applied for making muffs, coats, and fur-trimmings to garments. The fur is not separated from the pelt for these purposes; the two are used together; and the pelt is converted into a kind of leather to fit it for being so employed. The fur-hunters always exercise great care in drying the skins after removing them from the animals, seeing that any putrefactive action would ruin the fur. When brought to England, the skins undergo certain cleansing processes. They are steeped and scoured in a bath of bran, alum, and salt, to remove greasiness from the pelt; and then in a bath of soap and soda, to remove oiliness from the fur. When thoroughly washed and dried, it is found that the pelt, by the action of the alum, has been converted into a kind of *tanned* or kid leather.

When the skins are cleansed and dried, they are made up into garments and trimmings by sewing through the pelt. The skins, however, are very irregular in shape, and often differ much in color in different parts; they require to be cut up into pieces, matched according to tint, and sewn together edge to edge. This requires much skill, especially where the furs are of a valuable sort. A fur garment or trimming, appearing to the eye as if it were one uniform piece, is thus generally made up of many variously shaped pieces. The shaping for use, and the lining with silk and other materials, call for no description.—The great source of furs is the Hudson's Bay Territory (q. v.).

FURFURAMIDE, FURFURINE, AND FURFUROL. When starch, sugar, or bran is acted upon by dilute sulphuric acid and peroxide of manganese, the distillate contains not only Formic Acid (q. v.), but a small quantity of an essential oil, which, after being purified by redistillation, is colorless, has a fragrant odor somewhat resembling that of bitter almonds, and when dissolved in cold sulphuric acid, forms a beautiful purple liquid. This oil is termed Furfural, and its composition is represented by the formula $C_{10}H_8O_4$.

If furfural be treated with ammonia, it is converted into Furfuramide ($C_{10}H_{12}N_2O_4$), which occurs in colorless crystals, insoluble in water, but soluble in alcohol, and perfectly neutral.

If furfuranide is boiled with a solution of potash, it dissolves, its elements assume a new arrangement, and the solution on cooling deposits long silky needles of a powerfully alkaline base, Furfurine, which is isomeric with furfuranide. It is dissolved by dilute acids, and completely neutralizes them; and on adding ammonia to these solutions, the alkaloid is precipitated unchanged. It was discovered by the late Professor Fownes; and as the first vegeto-alkali artificially formed, its production was regarded as a great step in organic chemistry.

FURIDPU'R, a town of Bengal Proper, capital of a district of the same name, stands on the right bank of the Ganges, here called the Podda, in lat. $23^{\circ} 36'$ N., and long. $89^{\circ} 50'$ E. It is 115 miles to the north-east of Calcutta. Excepting the public establishments, which it possesses as the capital of the district of its own name, the place is mainly a scattered series of native villages; and, in fact, it claims notice chiefly as having at one time been a nest of river-pirates. Pop. (1872) 8593.

FURIDPU'R, or **DACCA JELALPUR**, the district mentioned in the preceding article, stretches in N. lat. between $23^{\circ} 3'$ and $24^{\circ} 5'$, and in E. long. between $89^{\circ} 30'$ and $90^{\circ} 15'$, containing 1496 sq. m., and (1872) 1,012,589 inhabitants. It is everywhere intersected by branches or feeders of the Ganges, which, as the surface barely rises above the level of the sea, are all, unless in the dry season, good for navigation. The soil is in general rich.

FURIES. See **EUMENIDES**.

FURLONG (the length of a furrow), a measure of length, the eighth part of a mile or 220 yards. See **YARD**.

FURLOUGH, a military term signifying leave of absence. Non-commissioned officers and private soldiers on furlough must be provided with a pass, or they are liable to be seized and dealt with as deserters.

FURNACES of various kinds (regenerator, reverberatory, Siemens's, &c.) are discussed in the articles **IRON**, **GLASS**, **LEAD**, &c.

FURNEAUX, the name of an English navigator, who was second in command on Cook's second voyage, is used of a group of islands in Bass's Strait, between Australia and Tasmania. Flinders Island, the principal one, is 46 miles long by 10 broad.

FURNES, a small town of Belgium, in West Flanders, lies 27 miles W.S.W. of Bruges, where four important lines of canal meet. The town-house is a fine Gothic structure. F. trades in linen, cattle, hops, and cheese. Pop. (1870) 4500.

FURNESS, a district in N.W. of Lancashire, forming a peninsula between Morecambe Bay and the Irish Sea. The chief town is Barrow-in-F. The ruin of F. ABBEY is situated in a beautiful glen two miles from Barrow, and is one of the finest examples of the transition Norman and Early English architecture in the country. Founded in 1127 for the Benedictines, it afterwards became a Cistercian house. It was long one of the wealthiest abbeys in the kingdom. The civil jurisdiction of the princely abbots of F. extended beyond the limits of the district of Furness.

FURNITURE, the name of an organ-stop or register, consisting of two or more ranks of pipes to each note, all of a higher pitch than the 15th stop.

FURNITURE, HOUSEHOLD, HIRING OF. If a man lets out furniture for immediate use, there is an implied warranty that it is fit for use, and free from all defects inconsistent with the reasonable and beneficial enjoyment of it. *Sutton v. Temple*, 12; *Meason and Welsby*, 60. The hirer must use the furniture for a proper purpose. If it is applied to a purpose inconsistent with the terms of the contract, or if it is sold by the hirer, the owner is entitled to maintain an action for its value. These general rules may be regarded as prevailing both in England and Scotland. In case of wilful injury done to furniture by a tenant within the metropolitan police district, it is provided by 2 and 3 Vict. c. 71, s. 38, that the police magistrate may award compensation to the amount of £15. In England as well as Scotland, the use of furniture for life is often made the subject of a bequest; and in this case, allowance will be made for ordinary wear and tear in the use of the furniture.

Lien on Furniture for Rent.—As a general rule, all furniture found on the premises, whether the property of the tenant or of a third party, may be distrained for rent, on the principle that the landlord has a lien over it in respect of the place in which it is found, and not in respect of the person to whom it belongs. To this rule there are some exceptions in favor of trade, as of tools in actual use, &c. In Scotland, the landlord has a similar right over the furniture in a house, so that hired furniture may be seized; but furniture lent without payment of rent does not fall under this Hypothec (q. v.). Even where furniture has been sold, the landlord has a claim over it while it remains on the premises.

FURRUCKABAD (Happy Residence), a city of the Doab (q. v.), stands near the right bank of the Ganges, in lat. $27^{\circ} 24'$ N., and long. $79^{\circ} 40'$ E. It is a handsome, clean, and healthy place, 570 feet above the level of the sea, with a considerable trade, and a population of (1871) 79,204. Independently of its position on the grand artery of the country, F. is within 20 miles of the great route between Calcutta and Delhi. Here Lord Lake defeated the troops of Holkar in 1805.

FURRUCKABAD, the district of which the city of the same name is the capital, in the N.-W. Provinces, stretches in N. lat. between $26^{\circ} 46'$ and $27^{\circ} 43'$, and in E. long. between $78^{\circ} 57'$ and $80^{\circ} 2'$. With a population of (1871) 918,784, it contains only 1702 sq. m., scarcely one-twelfth of the area being beyond the limits of the Doab. The commercial crops are principally cotton, tobacco, and indigo.

FURS, in Heraldry. Shields being often covered with the skins of wild animals, on which the fur was left, there came to be certain kinds of fur which were used in coat-armor, as well as in trimming and lining the robes of knights and nobles, and the mantles which were represented as surrounding their shields. The principal heraldic furs are—1. Ermine of which the field is white, and the spots black; 2. Ermines of which the field is black, and the spots white; 3. Erminois which has the field gold, with black spots; 4. Vair, which consisted of pieces of the shape of little glass pots (Fr. *verres*, of which the word is a corrupt spelling). It is said that the furriers used such glasses to whiten furs in, and because they were generally of an azure (blue) color, the fur in

question came to be blazoned *argent* and *azure*; whilst counter-vair, in which the cups are represented as placed base against base, in place of edge to base, as in *vair* was *or* and *azure*. 5. Potent

FURS.

Potent. Counter-vair. Vair. Ermine.

and counter-potent, which are supposed to resemble the heads of crutches, placed differently, but having the same tinctures—viz., *azure* and *argent*.

FÜRST, JULIUS, a distinguished orientalist of Jewish parentage, was born 12th May 1805, at Zerkowa, in the grand-duchy of Posen, Prussia, where his father was Lecturer on Circumcision in the synagogue. F. was educated for the rabbinical profession, and displayed at a very early age a most remarkable power of acquiring knowledge. He studied at Berlin, where the German philosophy made sad havoc of his previous convictions. The conflict in his mind between science and rabbinical lore ended, in 1829, in the defeat of the latter, and F. immediately proceeded to Breslau, where he continued his oriental, theological, and antiquarian studies, which were completed at Halle in 1831, under Gesenius, Wegscheider, and Tholuck. In 1833 he went to Leipzig, where he became professor in the university in 1864. Among his numerous and valuable writings may be mentioned *Lehrgebäude der Aramäischen Idiome* (System of Aramaic Idioms, Leip. 1835), a work which brought the Semitic languages within the sphere of comparative grammar, then in its infancy, and which, besides, sought to establish a system of analytic-historic investigation in regard to these languages themselves; *Perlenschnüre Aramäischer Gnomén und Lieder* (Pearl-strings of Aramaic Gnomes and Songs, Leip. 1836), with elucidations and glossary; *Concordantie Librorum Sacrorum Veteris Testamenti Hebraice et Chaldaice* (Concordances of the Sacred Books of the Old Testament in Hebrew and Chaldaic, Leip. 1837–1840), a work of indefatigable industry and careful research, which has obtained for its author a great reputation both in Germany and other countries; *Ari Nohem* (Leip. 1840), a polemical treatise on the genuineness of the Sohar and the worth of the Cabbala; *Die Sprüche der Väter* (The Sayings of the Fathers, Leip. 1839); *Die Israelitische Bibel* (The Hebrew Bible, Berlin, 1838), translated into German from the original, by himself, in conjunction with other scholars; *Der Orient; Berichte, Studien und Kritiken für Jüdische Geschichte und Literatur* (The East; Notices, Studies, and Criticisms in connection with Jewish History and Literature, Leip. 1840); *Die Jüdischen Religionsphilosophen des Mittelalters* (The Jewish Religious Philosophers of the Middle Ages, Leip. 1845); *Geschichte der Juden in Asien* (History of the Jews in Asia, Leip. 1849); *Bibliotheca Judaica* (1849–1853); *Hebräisches und Chaldaisches Handwörterbuch* (Hebrew and Chaldaic Manual, Leip. 1851–1854); and an edition of Winer's *Chaldee Reading-Book* (1864). He died in 1873.

FÜRSTENWALDE, a small walled town of Prussia, in the province of Brandenburg, on the right bank of the Spree, 30 miles east-south-east of Berlin. It has a brick church of the 14th c., the *Marienkirche*, which contains a fine Gothic *Sacramentshäuschen* (or pyx for keeping the host), built of sandstone, and dating from 1510. F. manufactures linens and woollens, and carries on some trade by river. Pop. (1880) 10,781.

FÜRTH, a flourishing manufacturing town of Bavaria, in Middle Franconia, is situated at the confluence of the Rednitz and the Pegnitz, about 5 miles north-west of Nürnberg, with which it is connected by a railway, laid out in 1835, and the first that was completed in Germany. It has numerous churches, synagogues, a town-hall, theater, &c. It is the most industrious and most prosperous manufacturing town of Bavaria; its mirrors, chandeliers, snuff-boxes, lead-pencils, its brass and wood wares, and its articles of dress, are famous. The making of metallic leaf, and the manufacture of articles in bronze, are most important branches of industry. F. also produces pinchback rings, watch-keys, brass nails, spectacles, and optical instruments, in great abundance. An annual fair, lasting fourteen days takes place at Michaelmas. Pop. (1880) 31,063, of whom 4000 are Jews, and the rest Protestants. F. first appears in history about the beginning of the 10th c., when it belonged to the archbishops of Bamberg. Subsequently it acknowledged the authority of the Burgrafs of Nuremberg. In 1634, during the Thirty Years' War, the Austrian Croats burned it to the ground. In 1680, a great fire almost laid it in ashes again. It first began to attain importance as a seat of manufactures in the latter half of the last century.

FURY AND HECLA STRAIT, lying in lat. 70° N., and long. from 82° to 86° W., separates Melville Peninsula on the south from Cockburn Island on the north, and connects Fox's Channel on the east with the Gulf of Boothia on the west. It is of no value whatever as a means of communication, nor is ever likely to be so, its western entrance having been ascertained by Captain Parry, who discovered it, on his second voyage, to be impenetrably closed from shore to shore by the accumulated ices of many years. It is traversed from west to east by a strong current, which passes down Fox's Channel into Hudson's Strait.

FURZE (*Ulex*), a genus of plants of the natural order *Leguminosae*, sub-order *Papilionaceae*, distinguished by a two-leaved calyx with a small scale or bractea on each side of the base, stamens all united by their filaments, and a turgid pod scarcely longer than the calyx. The **COMMON F.** (*U. Europaeus*), also called **WHIN** and **GORSE**, is a shrub about two or three feet high, extremely branched; the branches green, striated, and terminating in spines; the leaves few and lanceolate; the flowers numerous, solitary, and yellow. It is common in many of the southern parts of Europe and in Britain, although it does not reach any considerable elevation on the British mountains, and often suffers from the frost of severe winters; whereas in mild seasons its flowers may be seen all winter, so that there is an old proverb, 'Love is out of season when the furze is out of blossom.' It is scarcely known in any of the northern parts of Europe; and Linnaeus is said to have burst into exclamations of grateful rapture when he first saw a common covered with F. bushes glowing in the profusion of their rich golden flowers. F. is sometimes planted for hedges, but is not well suited for the purpose, occupying a great breadth of ground, and not readily acquiring sufficient strength; besides, it does not, when cut, tend to acquire a denser habit. It is useful as affording winter food for sheep, and on this account is burned down to the ground by sheep-farmers when its stems become too high and woody, so that a supply of green succulent shoots may be secured.

In some parts of Wales, F., chopped and bruised, forms the principal part of the winter fodder of horses. In some places, it is sown to yield green food for sheep or other animals, but is preferable to other green crops only on dry sandy soils, where they could not be advantageously cultivated. It is most extensively cultivated in Flanders. It is chopped and bruised by means of a mallet, one end of which is armed with knife-blades; or by means of a simple machine, called a gorse-mill.—A double-flowering variety is common in gardens. A very beautiful variety, called **IRISH F.**, because originally found in Ireland (*U. strictus* of some botanists), is remarkable for its dense, compact, and erect branches. A dwarf kind of F. (*U. nanus*) occurs in some places, and is perhaps also a mere variety; if so, there is only one species known.

In fox-hunting countries, F. is encouraged on account of the excellent cover it affords. It is also a favorite cover for rabbits.

FUSARO, LAKE OF, a small lake of South Italy, in the province of Naples, 11 miles west from Naples, on the peninsula of Baiæ. It is not far from the site of the ancient Cumæ, of which it is supposed to have been the port. Numerous remains of massive buildings, villas, and tombs are still to be seen in the neighborhood. At the southern extremity of the lake is a canal of Roman construction, communicating with the sea, now known as the *Foce del Fusaro*. The water of the lake is brackish, more salt than fresh. The lake is famous for its oysters, which have been cultivated here (see **OYSTER**) since the times of the ancient Romans. They are larger and of finer flavor than those of the Bay of Naples. The lake is supposed to be the crater of an extinct volcano; and, in 1838, great quantities of noxious gases were emitted, by which the oysters of the lake were killed. The lake of F. received from the ancients the name of *Acherusia Palus*, probably at first bestowed on it by the Greeks of Cumæ in consequence of its proximity to Avernus, and its crater-like character. In the later times of the Roman Empire, however, its banks were adorned with the villas of wealthy Romans.

FUSE, **FUSEE**, a tube of wood or metal, perforated down the side with a vertical row of holes, and used for firing shells. The tube is filled with a composition of nitre, sulphur, and gunpowder, which will burn gradually. The distance between each hole representing a second, the range and time of flight are computed, and that hole is left open which will communicate the fire in the fuse to the loaded shell at the moment the latter touches the ground after being discharged. Of course, when combustion reaches this aperture, the shell is burst by the explosion of the contained gunpowder, and scattered around in numerous fragments. Fuses constructed on a similar principle are used in exploding military mines (q. v.).

FUSEL or **FOUSEL OIL**, known as a **POTATO SPIRIT**, is a frequent impurity in spirits distilled from fermented potatoes, barley, rye, &c., to which it communicates a peculiar and offensive odor and taste, and an unwholesome property. Being less volatile

than either alcohol or water, it accumulates in the last portions of the distilled liquor. According to Liebig, it is principally formed in the fermentation of alkaline or neutral liquids, while it never occurs in acidulous fermenting fluids which contain tartaric, racemic, or citric acid. It mainly consists of a substance to which chemists have given the name of amylic alcohol, whose composition is represented by the formula $\text{HO}, \text{C}_{10}\text{H}_{19}\text{O}$. It is a colorless limpid fluid, which has a persistent and oppressive odor and a burning taste. It is only sparingly soluble in water, but may be mixed with alcohol, ether, and the essential oils in all proportions. Any spirit which produces a milky appearance, when mixed with four or five times its volume of water, may be suspected to contain it.

Fusel oil is principally sold in this country for the purpose of yielding pear essence for the so-called jargonelle-drops; it has likewise been patented as a solvent for quinine; and according to Liebig, it is sometimes employed in lighting distillery buildings.

FUSELI, HENRY, the second son of John Caspar Fuseli, or Fuessli, a portrait-painter, and author of *Lives of the Swiss Painters*, was born at Zurich in 1742. He studied in his native town and at Berlin, travelled with Lavater in 1761, and then went to England, where, by Reynolds's advice, he devoted himself to art. In pursuance of this object, he proceeded to Italy in 1770, where he remained for eight years, studying in particular the works of Michael Angelo and in 1778 returned to England. In 1790 he was elected a member of the Royal Academy, where, nine years later, he became professor of painting. He died at Putney Hill, near London, 16th April 1825, and was buried beside his friend, Sir Joshua Reynolds, in St. Paul's. His most remarkable works are 'The Ghost of Dion,' from Plutarch; 'Lady Macbeth,' 'Hercules and the Horses of Diomedes,' and his 'Milton's Gallery,' comprising 47 designs from *Paradise Lost*. F.'s imagination was bold, but coarse; he had more genius than art; and his execution was often spasmodic in the extreme. His art criticism, however, strange to say, ranks among the best in the language. His literary works, with a narrative of his life, were published by Knowles (3 vols., London, 1831).

FUSIBILITY. With few exceptions, all solids which can bear a high temperature without undergoing chemical change, may be melted. Many substances which are popularly regarded as infusible—as, for example, platinum and flint—readily fuse before the oxyhydrogen blow-pipe, or between the poles of a powerful galvanic battery; even carbon has been partially fused by the last-named means. There are many substances which cannot be melted because they are decomposed by the action of heat. Thus, wood and many other organic compounds are decomposed into certain gases, which escape, and into carbon and fixed salts, which are left. Similarly, carbonate of lime (chalk) is decomposed into carbonic acid gas and lime at a temperature below its fusing-point. If, however, we prevent the gas from escaping by confining the carbonate of lime in a hermetically closed gun-barrel, it can be melted at a high furnace-heat.

A table of 'The Order of Fusibility of the Metals' is given by Miller in his *Elements of Chemistry*, 2d edition, vol. ii. p. 294.

FUSING AND FREEZING POINTS are terms applied to the temperature at which solids assume the liquid form, and liquids become solid. The following table gives some of the best determinations of the fusing-point:

Mercury.....	—39°	Alloy (1Sn,2Bi).....	286°
Oil of vitriol.....	—30°	“ (3Sn,2Pb).....	333°
Bromine.....	9°·5	Tin.....	451°
Oil of turpentine.....	14°	Bismuth.....	512°
Ice.....	32°	Nitrate of soda.....	591°
Lard.....	91°	Lead.....	620°
Phosphorus.....	111°·5	Nitrate of potash.....	642°
Potassium.....	136°	Zinc.....	773°
Yellow wax.....	143°·6	Antimony, (about).....	900°
Stearic acid.....	158°	Silver.....	1773°
Sodium.....	207°·7	Copper.....	1996°
Fusible metal (5Pb,3Sn,8Bi).....	212°	Gold.....	2016°
Iodine.....	226°·4	Cast iron.....	2786°
Sulphur.....	239°	Wrought iron, higher than.....	3280°

We see from this table that alloys may have a fusing point far below that of any of the metals which enter into their composition. Similarly, mixtures of various silicates, fuse at a temperature far below that which is required to melt any one of them, and the same remark applies to mixtures of various chlorides, carbonates, &c.

Most solids when heated to their fusing-point, change at once into perfect liquids; but some—as, for example, platinum, iron, glass, phosphoric acid, the resins, and many others—pass through an intermediate pasty condition before they attain perfect fluidity, and, in these cases, it is difficult, if not impossible, to determine the exact fusing point. This intermediate condition is termed

vitreous fusion, because it is a characteristic property of glass. It is in this intermediate state that glass is worked, and iron and platinum forged.

As a general rule, the freezing-point is the same as the fusing-point—that is to say, if a substance in the liquid form be cooled below the fusing-point, it again becomes solid; but there are cases in which we can cool a liquid several degrees below its fusing-point; thus, by keeping water perfectly still, we can cool it to 5°, or even to 1°·4 before it freezes. If, however, we drop a solid body into water in this condition, or if we shake the vessel containing it, congelation begins at once, and the temperature rises to 32°. This phenomenon is exhibited to a still greater degree in viscid fluids, like the oils. It is well known that the freezing-point of water is depressed by the presence of salts. Thus, sea-water freezes at about 26°·6, and a saturated solution of common salt must be cooled as low as 4° before freezing. Despretz has given the freezing-points of various saline solutions at different degrees of concentration in the fourth volume of the *Comptes Rendus*, p. 435.

FUSIBLE METAL. Fusible metal is composed of 2 parts of bismuth, 1 of lead and 1 of tin. It fuses at 201° F., becoming pasty before it completely melts. It expands in a very anomalous manner; its bulk increases regularly from 32° to 95°; it then contracts gradually to 131°; it then expands rapidly till it reaches 176°, and from that point till it melts, its expansion is uniform. The faculty of expanding as it cools, while still in a comparatively soft state, renders the alloy very serviceable to the die-sinker, who employs it to test the accuracy of his die, every line being faithfully reproduced in the cast made of the alloy. The proportions of the three metals are sometimes varied, and another formula is given in the table in FUSING AND FREEZING POINTS.

FUSIL (Fr. *fusée*, a spindle) is represented heraldically as longer and more acute than a Lozenge (q. v.).

FUSILIER'S were formerly soldiers armed with a lighter fusil or musket than the rest of the army; but at present all regiments of foot carry the improved rifle. Fusilier is therefore simply a historical title borne by a few regiments—viz., the Scots Fusilier Guards, the 5th Northumberland, 7th Royal, 21st North British, 23d Welsh, 87th Irish, 101st and 104th Bengal, 102d Madras, and 103d Bombay Fusiliers.

FU'STIAN, a cotton fabric having a pile like velvet, but shorter, and which is manufactured in nearly the same manner as velvet—viz., by leaving loops standing upon the face of the fabric, and then cutting them through so as to form upright threads, which are afterwards smoothed by shearing, singeing, and brushing. See VELVET; also MOLESKIN AND CORDUROY.

FUSTIC, a name given to two kinds of dye-wood used for producing a yellow color, and with chemical additions, other colors, such as brown, olive, and green. The French name *Fustec* seems to be connected with *Fustet*, a kind of sumach found in the south of Europe; and to have been transferred to a very different plant, the *Maclura tinctoria* of Don, or *Morus tinctoria*, a tree of the natural order *Moraceæ*, a native of the West Indies, Mexico, Brazil, Columbia, &c. The fustic is a large and handsome tree, the wood is of a greenish-yellow color, and is sometimes used in mosaic-cabinet-work and turning, but chiefly in dyeing. About 10,000 tons are imported annually into Britain. The tree is particularly abundant in Campeachy. The wood contains a great quantity of coloring matter, which forms the most durable of vegetable yellow dyes; but as the color is rather dull, it is more used for producing other colors. The name OLD FUSTIC is sometimes given to it, and YOUNG FUSTIC to the wood of *Rhus cotinus*. These terms began to be employed about the beginning of last century, from the mistaken notion that the one, in small pieces, was the wood of the young tree, and the other, in comparatively large logs, of the same tree in a more mature state.—The OSAGE ORANGE (q. v.) of North America (*Maclura aurantiaca*) is nearly allied to old fustic, and its wood also affords a yellow dye.

OLD FUSTIC, or Yellow Wood, is employed for dyeing woollens yellow, and also to impart to them green and olive colors when mixed with indigo and salts of iron. It furnishes a yellow coloring matter, which may be obtained in crystals by evaporating its watery solution. This substance is termed moritannic acid, and its composition is represented by the formula $\text{C}_{20}\text{H}_{16}\text{O}_{20}$. The bichromates of potash and of lead have to a great degree superseded the use of OLD FUSTIC.

YOUNG FUSTIC is the wood of *Rhus cotinus* or *Venetian sumach*. It contains a yellow coloring matter, to which the name *Fusteric* has been given. It is generally used in combination with other dyes in order to strike some particular tint.

FUSUS (Lat. a spindle), a genus of gasteropodous molluscs nearly allied to *Murex* (q. v.), having a spindle-shaped shell, with a very elevated spire, the first whorl often much dilated, and a straight elongated canal. The whorls are not crossed by varices, as in *Murex*. The species were formerly, however, included in

that genus. About 100 existing species have been described, and more than threetimes that number of fossil ones. The existing species are distributed over the whole world, living generally on muddy and sandy sea-bottoms at no great depths. *F. antiquus* is known in the south of England as the RED WHELK, and in Scotland as the ROARING BUCKIE, from the continuous sound—as of waves breaking on the shore—heard when the empty shell is applied to the ear. In the cottages of Zetland, the shell, generally about six inches long, is used for a lamp, being suspended horizontally by a cord, its cavity containing the oil, and the wick passing through the canal. This mollusc is often dredged up with oysters. It is eaten by the poor, but is more generally used as bait for cod, skates, &c.

This genus makes its first appearance in the Oolite, in which 10 species have been noticed. The numbers increase to 35 in the Cretaceous rocks, to 100 in the Eocene, and to 150 in the Miocene and Pliocene.

FUTAK, a town of Lower Hungary, in the county of the Lower Baes, is situated on the left bank of the Danube, in lat. 45° 15' N., and long. 19° 42' W. It has a beautiful castle and garden, and the inhabitants grow vegetables and tobacco extensively. F. has a great trade in corn, and has a fair in November, frequented by merchants from Turkey, Greece, and Armenia. Pop. (1880) 5367.

FUTEHGU'NGE (in English, *Victory Market*) is the name of two places in Rohilkund, the scenes respectively, as the name implies, of two battles gained by the British over the Rohillas.—1. *Eastern F.*, a town of the district of Bareilly, is situated near the right bank of the Bhagal, in lat. 28° 4' N., and long. 79° 42' E. The action, from which this spot is designated, was fought in 1774, giving to the Nawab of Oude, then an ally of the English East India Company, a large part of Rohilkund; and it was, in fact, to commemorate that event, that Eastern F. was built by that prince.—2. *Western F.*, a town also of the district of Bareilly, is situated in lat. 28° 28' N., and long. 79° 24' E. The conflict that distinguished this locality occurred in 1796. The only eminence in the neighborhood, the most hotly contested point in the struggle, bears twofold testimony to the story, in the memorials of those who fell—a plain and simple monument of fourteen British officers, and a carved and minareted tomb of two Rohilla chieftains.

FUTTEHPUR, a town of the Doab, N.-W. Provinces, on the great trunk-road between Calcutta and Delhi, stands in lat. 25° 51' N., and long. 80° 54' E., 70 miles north-west of Allahabad, and 50 miles to the south-east of Cawnpore. It is a thriving place, with (1871) 20,478 inhabitants. Besides the buildings belonging to the civil establishment of the district of its own name, it contains a small but very elegant mosque.

FUTTEHPUR, the district of which the town of the preceeding article is the capital, lies wholly within the Doab, and occupies its entire breadth from Jumna to Ganges. It extends immediately to the west of the district of Allahabad, in lat. from 25° 25' to 26° 13' N., and in long. from 80° 12' to 81° 23' E., containing 1583 square miles, and (1871) 663,815 inhabitants. It yields large quantities of cotton, and by means of its bordering rivers, and a branch of the Ganges Canal, it possesses considerable facilities for inland navigation.

FUTTUHA, or FUTWA, a town of (1871) 11,295 inhabitants, in the district of Patna, and presidency of Bengal, stands at the confluence of the Punpun and the Ganges, in lat. 25° 30' N., and long. 85° 22' E. As the Ganges is here deemed peculiarly sacred, F. is, at certain seasons of the year, the resort of vast numbers of pilgrims.

FUTTYGU'RH, the military cantonment of Furruckabad, stands about three miles to the east of that city, on the opposite or left bank of the Ganges, being in lat. 27° 22' N., and long. 79° 41' E. Its name became peculiarly famous, or rather infamous, in the mutiny of 1857, less, however, for the outbreak that occurred on the spot, than for the unparalleled sufferings of the hapless fugitives—men, women, and children. Pop. (1871) 10,335.

FUTTYPU'R, a town in the district of Saugur, and chief-commissionership of the Central Provinces, stands on the Union, a tributary of the Nerbudda, about 20 miles from the point of junction, being in lat. 22° 38' N., and long. 78° 38' E. It is a place of some importance, as being the residence of three Gond rajahs.

FUTURE DEBT is a debt wherein the obligation to pay and the time for payment is fixed and certain, but the day for performance has not arrived. Of such a debt, it was said in the civil law *dies cedit etsi nondum venerit*; and it was distinguished from

a contingent debt, i. e., a debt payable on the performance of a condition which was uncertain, in which it was said *dies nec cedit nec venit*. Thus, an obligation to pay six months hence is a future debt; an obligation to pay 'if my ship returns from Spain,' is contingent. In the event of the death or bankruptcy of a person having large commercial transactions, it is often of great importance that the right of the holders of such securities should be accurately fixed. In Rome, on the death or bankruptcy of a citizen, a creditor holding a claim for a future debt was entitled to payment, deducting a percentage proportionate to the date at which his debt was payable; but a contingent creditor only received a security for payment in case his debt should become payable. This general principle has been introduced into the legal systems of modern states. In Holland and in France, the rights of creditors having claims not immediately payable are based upon the rule of the civil law.

In England, a future debt, in order to found a valid claim, must be in writing, but it may be constituted by bond, bill, or note or other security. By common-law, such a claim could not be enforced until the actual time for payment has arrived; and formerly, in case of bankruptcy, a creditor on a debt of this kind was not allowed to insist in his claim. At the same time, the bankrupt's discharge was held not to release him for a debt which had not been admitted to claim in the process; and hence debtors were sometimes incarcerated for years on debts which they were wholly unable to discharge. See IMPRISONMENT FOR DEBT. This state of things was productive of manifest injustice on both debtor and creditor; on the latter, by excluding him from insisting in his claim at a time when he might have obtained a partial payment; on the former, by punishing him for his default when he was deprived of the means of making any return. The subject was frequently discussed in parliament before a remedy was applied. At last, by 6 Geo. IV. c. 16, s. 51, it was enacted that, in cases of bankruptcy, where a debt was not immediately payable, the creditor should be entitled to prove his debt and receive a dividend, deducting interest at 5 per cent. for the period which was to elapse before the date when the debt was payable in due course. By s. 56, debts payable on a contingency might be valued, and a dividend paid on the estimated value. Similar provisions were inserted in the 12 and 13 Vict. c. 196, ss. 172 and 177. By the last bankruptcy act, 24 and 25 Vict. c. 134, s. 153, it is enacted that a person having a claim for unliquidated damages, which are of the nature of a future debt, may have his claim assessed by a jury either in the court of equity, or before a common-law judge, or, in case of agreement between the parties, by the court without a jury.

By the common law of Scotland, the rule of the civil law, as to the rights of creditors having a future claim, has always been recognized. In the event of bankruptcy, creditors in both future and contingent debts are allowed to rank, but the latter only to the extent of receiving a security until the condition is purified. But by 19 and 20 Vict. c. 79, s. 53, which is now the ruling statute as to bankruptcy in Scotland, contingent creditors may have their debts valued, and may vote in the Sequestration (q. v.), and draw dividends proportionate to the valuation. It is also enacted, s. 14, that all creditors whose debts are not *contingent* may concur in the petition for bankruptcy. But the Scotch law affords to future debtors a further privilege, unknown to the system of the sister-country—viz., that of arrestment in security, whereby a creditor having a future claim is enabled, in case his debtor seem to be wilfully diminishing his means of discharging his debt, to attach the goods of the debtor as a security for the payment of his debt. See ARRESTMENT.

FYNE, LOCH, an arm of the sea running north and north-east from the Sound of Bute in the south of Argyshire, to beyond Inverary, in the north, and is bounded by the district of Cowal on the E., and by those of Argyre, Knapdale, and part of Cantire on the W. It is 43 miles long, 2 to 10 miles broad, and 40 to 70 fathoms deep. Its shores are deeply indented, and bordered by low bare hills, which rise higher and are wooded near Inverary. On the west side, it sends off a small branch leading to the Crinan Canal. Loch F. is celebrated for its herrings.

FYZABA'D, a rapidly decaying city of Oude, stands on the right bank of the Ghogra, here a navigable river, in lat. 26° 47' N., and long. 82° 10' E. Originally an appendage, as it were, of Ayodha or Oude, the ancient capital from which the country took its name, F. became, in 1730, itself the seat of government. But in 1775, immediately after the annexation of part of Rohilkund (see FUTEHGU'NGE), it was supplanted by Lucknow, which lay about 90 miles to the west, in the direction of the newly acquired territory. Pop. (1871) 37,804.
